28 A Foundation of Diffusion Models

29 A.1 SDEs/ODEs and Solvers

30 Assume a D -dimensional random variable $\mathbf{x}_0 \sim \mathbb{R}^D$ with an unknown distribution $q_0(\mathbf{x}_0)$ ¹. Diffu-
 31 sion Models (DMs) [24, 47] define a *forward process* $\{\mathbf{x}_t\}_{t \in [0, T]}$ with $T > 0$ by the *noise schedule*
 32 $\{\alpha_t, \sigma_t\}_{t \in [0, T]}$, such that $\forall t \in [0, T]$, \mathbf{x}_t satisfies

$$\mathbf{x}_t = \alpha_t \mathbf{x}_0 + \sigma_t \boldsymbol{\epsilon}, \quad \boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \mathbf{I}), \quad (1)$$

33 where $\alpha_t, \sigma_t \in \mathbb{R}^+$ are differentiable functions of t and the *signal-to-noise-ratio* (SNR) α_t^2/σ_t^2 is
 34 strictly decreasing w.r.t t . The forward process in Equation (1) can also be described as a stochastic
 35 differential equation (SDE) for any $t \in [0, T]$ [24]:

$$d\mathbf{x}_t = f(t)\mathbf{x}_t dt + g(t)d\mathbf{w}_t, \quad \mathbf{x}_0 \sim q_0(\mathbf{x}_0), \quad (2)$$

36 where $\mathbf{w}_t \in \mathbb{R}^D$ is the standard Wiener process, and $f(t) = \frac{d \log \alpha_t}{dt}$, $g^2(t) = \frac{d\sigma_t^2}{dt} - 2\sigma_t^2 \frac{d \log \alpha_t}{dt}$. The
 37 SDE forward process in Equation (2) has an equivalent *reverse process* from time T to 0 [47]:

$$d\mathbf{x}_t = [f(t)\mathbf{x}_t - g^2(t)\nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t)]dt + g(t)d\bar{\mathbf{w}}_t, \quad \mathbf{x}_T \sim q_T(\mathbf{x}_T), \quad (3)$$

38 where $\bar{\mathbf{w}}_t$ is a standard Wiener process in the reverse time. One can sample $q_0(x_0)$ by directly solving
 39 the SDE in ??, in which the only unknown term is the *score function* $\nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t)$. In practice, a
 40 neural network $\boldsymbol{\epsilon}_\theta(\mathbf{x}_t)$ parameterized by θ can be trained to approximate the scaled score function
 41 $-\sigma_t \nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t)$ by minimizing the score matching loss [19, 46, 47]:

$$\mathcal{L}(\theta) := \mathbb{E}_{t \sim \text{Uniform}(0, T), \mathbf{x}_t \sim q_t(\mathbf{x}_t)} [\|\boldsymbol{\epsilon}_\theta(\mathbf{x}_t, t) + \sigma_t \nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t)\|_2^2] \quad (4)$$

$$= \mathbb{E}_{t \sim \text{Uniform}(0, T), \mathbf{x}_0 \sim q_0(\mathbf{x}_0), \boldsymbol{\epsilon} \sim \mathcal{N}(\mathbf{0}, \mathbf{I})} [\|\boldsymbol{\epsilon}_\theta(\mathbf{x}_t, t) - \boldsymbol{\epsilon}\|_2^2]. \quad (5)$$

42 Since $\boldsymbol{\epsilon}_\theta(\mathbf{x}_t, t)$ can be considered as a predicted Gaussian noise added to \mathbf{x}_t , it is usually called
 43 the *noise prediction model*. With a well-trained noise prediction model, SDE in ?? can be solved
 44 using numerical solvers, and DDPM [19] is one such method. However, numerical solvers require
 45 discretization from T to 0, in which the randomness of the Wiener process limits the step size [25].
 46 For faster sampling, one can solve the following *probability flow* ODE, which is proven to have the
 47 same marginal distribution as that of the SDE for any $t \in [0, T]$ [47]:

$$\frac{d\mathbf{x}_t}{dt} = f(t)\mathbf{x}_t - \frac{1}{2}g^2(t)\nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t), \quad \mathbf{x}_T \sim q_T(\mathbf{x}_T). \quad (6)$$

48 DDIM [46] discretizes the ODE to the first order for solving, achieving almost no loss in quality with
 49 fewer sampling steps. DPM-Solver [34, 35] leverages the semi-linearity of diffusion ODEs in ?? for
 50 exact solutions, eliminating errors in the linear terms, resulting in a higher sample quality. Some
 51 works also reformulate the framework. EDM [23] optimizes the design choices from a perspective of
 52 noise schedule and uses a specially designed score function preconditioning to improve the sample
 53 quality. Rectified flow [33], on the other hand, designs a straight probability flow ODE from the
 54 optimal transport (OT) perspective, which can straighten itself through *reflow* procedure. The straight
 55 property of Rectified flow allows high-quality generation in very few sampling steps.

56 A.2 Guided Sampling Methods

57 Guided sampling methods aim to draw samples from $q_0(\mathbf{x}_0|y)$ to generate outputs with the charac-
 58 teristics of the label y . Depending on whether an additional classifier needs to be trained, guided
 59 sampling methods are divided into two categories: classifier guidance (CG) [5] and classifier-free
 60 guidance (CFG) [20].

61 **Classifier Guidance:** For conditional sampling, the score function needs to be changed to
 62 $\nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t|y)$, which can be decomposed with the Bayes Theorem:

$$\nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t|y) = \nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t) + \nabla_{\mathbf{x}} \log q_t(y|\mathbf{x}_t), \quad (7)$$

¹To ensure clarity, we establish the convention that the subscript t denotes the timestep in the diffusion process, while the superscript t represents the timestep in sequential decision-making problem.

63 where the first term can be approximated by the noise prediction model, and the second term is a
 64 *noising classifier* that predicts the label y of the corrupt data \mathbf{x}_t . In practice, an additional neural
 65 network $\mathcal{C}_\phi(\mathbf{x}_t, t, \mathbf{y})$ is trained to approximate $\log q_t(\mathbf{y}|\mathbf{x}_t)$, and its gradient is computed to guide
 66 sampling process:

$$\bar{\epsilon}_\theta(\mathbf{x}_t, t, \mathbf{y}) = \epsilon_\theta(\mathbf{x}_t, t) - w\sigma_t \nabla_{\mathbf{x}} \mathcal{C}_\phi(\mathbf{x}_t, t, \mathbf{y}), \quad (8)$$

67 where w stands for the guidance scale. A larger value of w sharpens the classifier, amplifying the
 68 influence of the label y .

69 **Classifier-free Guidance:** According to Equation (7), the gradient of the classifier $\nabla_{\mathbf{x}} \log q_t(\mathbf{y}|\mathbf{x}_t)$
 70 can be written to $\nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t|\mathbf{y}) - \nabla_{\mathbf{x}} \log q_t(\mathbf{x}_t)$. By training a conditional noise prediction model
 71 $\epsilon_\theta(\mathbf{x}_t, t, \mathbf{y})$, the sampling process can be guided with no additional classifier:

$$\bar{\epsilon}_\theta(\mathbf{x}_t, t, \mathbf{y}) = \epsilon_\theta(\mathbf{x}_t, t) - w\sigma_t \nabla_{\mathbf{x}} \log q_t(\mathbf{y}|\mathbf{x}_t) = \epsilon_\theta(\mathbf{x}_t, t) + w(\epsilon_\theta(\mathbf{x}_t, t, \mathbf{y}) - \epsilon_\theta(\mathbf{x}_t, t)) \quad (9)$$

72 where $\epsilon_\theta(\mathbf{x}_t, t) = \epsilon_\theta(\mathbf{x}_t, t, \Phi)$ is approximated by the noise prediction model conditioned on a pre-
 73 specified label Φ standing for non-conditioning. Although CFG can generate trajectories specific to
 74 condition \mathbf{y} , it may cause the agent to reject higher likelihood trajectories in sequential environments,
 75 resulting in a performance drop [40]. Therefore, some methods [4, 40, 50] set the guidance weight w
 76 to 1, i.e., no guidance paradigm.

77 B Related Works

78 In recent years, DMs have demonstrated promising performance in various domains [51, 45, 32, 24],
 79 giving rise to several high-quality DM libraries, such as Diffusers [49] and Stable Diffusion [44].
 80 These open-source libraries have significantly promoted research and applications in related fields.
 81 However, unfortunately, these libraries are designed for multimedia such as image, audio, and video
 82 generation, lacking adaptation for decision-making tasks. This is likely because DMs play diverse
 83 roles in decision-making, with various usage patterns and many unique mechanism incorporations,
 84 creating a gap in the multimedia generation paradigm. A library specially designed for decision-
 85 making is currently missing, and most research codebases are inherited from a few pioneering
 86 studies [21, 50, 4]. While effective, their algorithm-specific mechanisms and tightly coupled system
 87 architecture make it challenging for customized development.

88 `CleanDiffuser` aims to provide an "easy-to-hack" starter kit for research needs, offering researchers
 89 more exploration possibilities. We draw from the experience of many open-source decision-making
 90 libraries. For example, we emulate `stable-baselines3` [43] to carefully reproduce results to provide
 91 practitioners with reliable baselines for method comparison. However, we inject more modular design
 92 to encourage users to freely design and modify. We also follow CORL [48] in designing clean and
 93 logically clear pipelines for readability, but, considering the complexity of DMs, abandon the one-file-
 94 from-scratch approach and opt for a one-file pipeline approach to offer rich examples of how to utilize
 95 `CleanDiffuser` building blocks to implement decision-making algorithms. Additionally, we follow
 96 Ray [30] in providing ample parameter selection interfaces within modules, making it easy for users
 97 unfamiliar with the internal implementation to customize effortlessly. In summary, `CleanDiffuser`
 98 is not only the first open-sourced modularized DM library tailored for decision-making algorithms
 99 but also a new library that draws on the advanced experiences of many open-source decision-making
 100 libraries.

101 C Details of Experimental Setup

102 C.1 Offline Reinforcement Learning Environments and Datasets

103 We evaluate 7 diffusion-based RL algorithms implemented with `CleanDiffuser` on 15 offline RL
 104 tasks from 3 benchmarks, including locomotion, manipulation, and navigation. These tasks are
 105 widely recognized and extensively used in offline RL settings [27, 10, 26, 16, 50, 22, 21, 1, 7, 29, 18],
 106 enjoying significant acceptance within the research community. Visualization of these tasks is

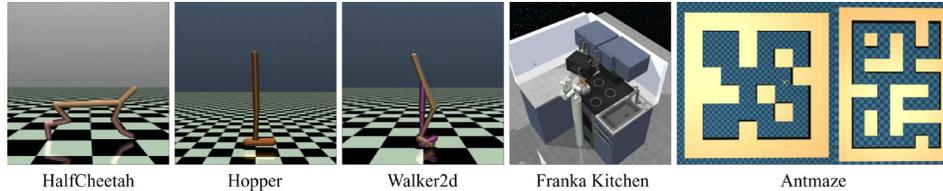

Figure 1: Visualization of Offline Reinforcement Learning Environments.

107 presented in Figure 1. These tasks come from the D4RL benchmark, in which the datasets are
 108 licensed under the Creative Commons Attribution 4.0 License (CC BY), and the code is licensed
 109 under the Apache 2.0 License.

110 **Gym-MuJoCo** [2] consists of three popular offline RL locomotion tasks (HalfCheetah, Hopper,
 111 Walker2d), which require controlling three Mujoco robots to achieve maximum movement speed
 112 while minimizing energy consumption under stable conditions. D4RL [9] benchmark provides three
 113 different quality levels of offline datasets: “medium” containing demonstrations of medium-level
 114 performance; “medium-replay” containing all recordings in the replay buffer observed during training
 115 until the policy reaches “medium” performance; and “medium-expert” which combines “medium”
 116 and “expert” level performance equally.

117 **Franka Kitchen** [11] requires controlling a realistic 9-DoF Franka robot arm to complete several
 118 household tasks in a kitchen environment. Algorithms are trained on “partial” and “mixed” datasets.
 119 The “partial” and “mixed” datasets consist of undirected data, where the robot performs subtasks
 120 that are not necessarily related to the goal configuration. In the “partial” dataset, a subset of the
 121 dataset is guaranteed to solve the task, meaning an imitation learning agent may learn by selectively
 122 choosing the right subsets of the data. The “mixed” dataset contains no trajectories that solve the
 123 task completely, and the RL agent must learn to assemble the relevant sub-trajectories. This dataset
 124 requires the highest degree of generalization in order to succeed.

125 **Antmaze** [9] requires controlling the 8-DoF “Ant” quadruped robot to complete maze navigation
 126 tasks. In the offline dataset, the robot only receives a reward upon reaching the goal, and the dataset
 127 contains many trajectory segments that do not lead to the endpoint, making it a difficult decision
 128 task with sparse rewards and a long horizon. The success rate of reaching the endpoint is used as the
 129 evaluation score, and common offline RL algorithms often struggle to achieve good performance.

130 C.2 Offline Imitation Learning Environments and Datasets

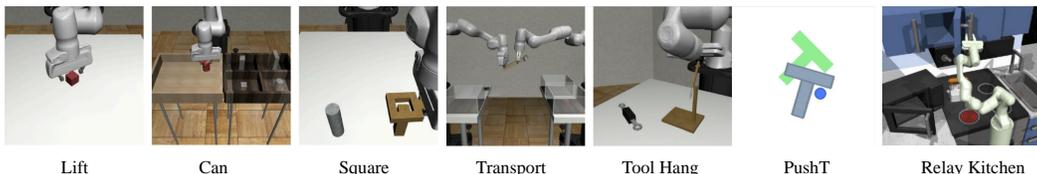

Figure 2: Visualization of Offline Imitation Learning Environments.

131 We evaluate 2 diffusion-based IL algorithms implemented with CleanDiffuser on 22 imitation learning
 132 tasks from 4 benchmarks, with both state and image-based observation inputs. Among them, Relay
 133 Kitchen and Robomimic support both velocity and position control. Each algorithm is trained with
 134 its best-performing action space. We provide task summary in Table 1, visualization in Figure 2, and
 135 more details below:

136 **PushT** [8] requires pushing a T-shaped block (gray) to a fixed target (red) with a circular end-effector.
 137 The task requires exploiting complex and contact-rich object dynamics to push the T block precisely,
 138 using point contacts. In this paper, we used three variants. “PushT” env has a five-dimensional
 139 state space, including the proprioception for end-effector location ($agent_x$, $agent_y$) and the

140 xy coordinates and angles of the blocks (`block_x`, `block_y`, `block_angle`). “PushT-keypoints”
 141 env includes nine 2D key points obtained from the T-block’s ground truth attitude and proprioception
 142 for end-effector location. “Pusht-image” env observes the end-effector location and the top view of
 143 the RGB image. This benchmark is licensed under the Apache-2.0 License.

144 **Relay Kitchen** is proposed in Relay Policy Learning [11], commonly used to evaluate imitative
 145 learning ability. The environment consists of a 9 DoF position-controlled Franka robot interacting
 146 with a kitchen scene that includes an openable microwave, four turnable oven burners, an oven
 147 light switch, a freely movable kettle, two hinged cabinets, and a sliding cabinet door. The “relay”
 148 dataset contains 566 human demonstrations, each completing four tasks in arbitrary order. The
 149 goal is to execute as many tasks as possible, regardless of order, showcasing both short-horizon and
 150 long-horizon multimodality. This benchmark is licensed under the Apache-2.0 License.

151 **Robomimic** [37] requires controlling a robot arm to complete complex manipulation tasks from a
 152 few human demonstrations. Due to the non-Markovian nature of human demonstrations and the
 153 demonstration quality variance, learning from human datasets is significantly more challenging
 154 than learning from machine-generated datasets. Proficient-Human (PH) and Multi-Human (MH)
 155 datasets are collected by humans through remote teleoperation. The PH datasets consist of 200
 156 demonstrations collected by a single, experienced teleoperator, while the MH datasets consist of
 157 300 demonstrations collected by 6 teleoperators of varying proficiency, each of which provided 50
 158 demonstrations. The benchmark consists of 5 PH tasks (Lift, Can, Square, Tool_hang, Transport) and
 159 4 MH tasks (Lift, Can, Square, Transport). Each task has both state and image-based observation
 160 inputs. This benchmark is licensed under the MIT License.

161 To the best of our knowledge, the datasets and benchmarks we have used do not contain personally
 162 identifiable information or offensive content in both previous works and our works.

Table 1: **Imitation Learning Task Summary.** Obs Shape represents the low dimensional state space dimension; Image Shape represents the observation resolution of multi-view images (Camera views x W x H). PH: proficient-human demonstration, MH: multi-human demonstration, Steps: max episode steps.

| Task | Low Dim Tasks | Image Tasks | | Action Dim | PH Demonstration | MH Demonstration | Max Steps |
|----------------|---------------|-------------|-------------|------------|------------------|------------------|-----------|
| | Obs Shape | Obs Shape | Image Shape | | | | |
| PushT | 5 | N/A | N/A | 2 | 200 | N/A | 300 |
| PushT-Keypoint | 20 | N/A | N/A | 2 | 200 | N/A | 300 |
| PushT-Image | N/A | 2 | 1x96x96 | 2 | 200 | N/A | 300 |
| Relay Kitchen | 60 | N/A | N/A | 9 | 656 | N/A | 280 |
| Lift | 19 | 9 | 2x84x84 | 7 | 200 | 300 | 400 |
| Can | 23 | 9 | 2x84x84 | 7 | 200 | 300 | 400 |
| Square | 23 | 9 | 2x84x84 | 7 | 200 | 300 | 500 |
| Transport | 59 | 18 | 4x84x84 | 7 | 200 | 300 | 700 |
| Tool_hang | 53 | 9 | 2x240x240 | 7 | 200 | N/A | 700 |

163 D Additional Experiments

164 D.1 Impact of Model Size in RL Benchmarks

Table 2: **Impact of Model Size in RL Benchmarks.** Performance of DD and IDQL with varying model sizes. Results correspond to the mean and standard error over 150 episode seeds.

| Environment | DD | | | IDQL | | |
|---|------------|-------------------|-------------------|------------|-------------------|-------------------|
| | 4M | 15M | 60M | 1.6M | 6M | 25M |
| HalfCheetah-m | 45.3 ± 0.3 | 44.5 ± 0.1 | 47.1 ± 0.1 | 51.5 ± 0.1 | 51.5 ± 0.1 | 51.7 ± 0.1 |
| Kitchen-m | 56.5 ± 5.8 | 80.5 ± 4.1 | 27.7 ± 2.1 | 66.5 ± 4.1 | 69.2 ± 1.0 | 67.5 ± 1.8 |
| Antmaze (mp for DD, lp for IDQL) | 8.0 ± 4.3 | 26.0 ± 5.9 | 22.7 ± 6.6 | 48.7 ± 4.7 | 52.0 ± 5.7 | 54.0 ± 4.3 |

165 There is a significant disparity in network model sizes used by diffusion-based decision-making
 166 algorithms. For instance, the official implementation of DD utilizes around 60M parameters [1], while
 167 Diffuser uses 4M [21], and IDQL [16] has approximately only 1.6M parameters. These works have

168 limited discussion on the impact of model size. Therefore, we aim to explore the approximate scale
 169 of parameter sizes required for diffusion-based decision-making algorithms to function effectively.
 170 In this experiment, we test DD and IDQL at three different model sizes, starting from the default
 171 parameter size used in the main experiments and gradually increasing the parameter size by four times.
 172 The performance of the algorithms is evaluated on three tasks including locomotion, manipulation,
 173 and navigation. Results are presented in Table 2. We find that, apart from the performance of DD
 174 on Kitchen-m and Antmaze-mp, increasing the model size does not lead to significant performance
 175 gains in other cases. However, even with the performance gains brought by model size, DD can not
 176 entirely catch up with the performance of IDQL, indicating that the dominant effect on performance
 177 is still primarily driven by the algorithm rather than the model size.

178 **D.2 Impact of Diffusion Backbones and Sampling Steps (Full Results)**

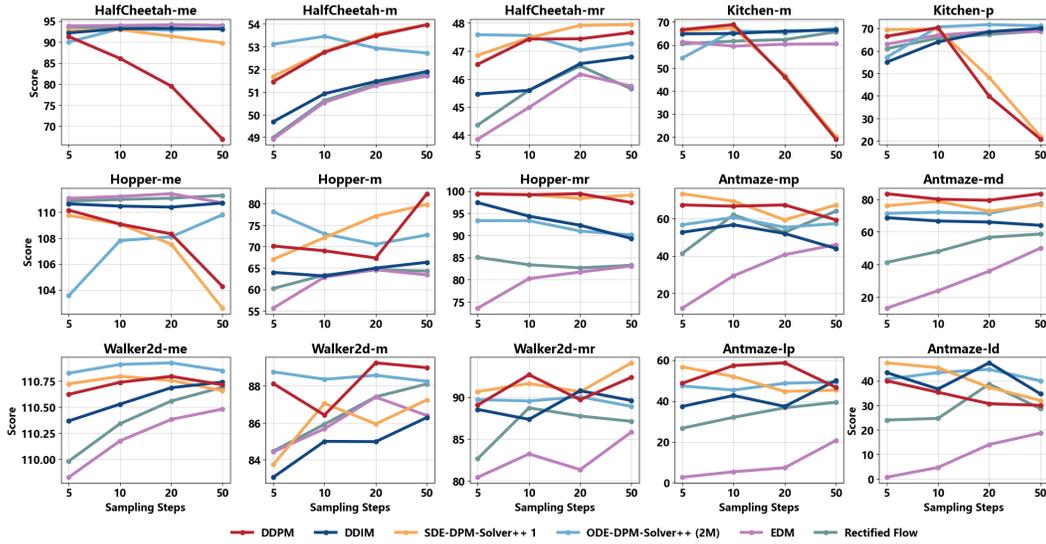

Figure 3: Full D4RL Results of IDQL. Performance of IDQL with various diffusion backbones and varying sampling steps. Results correspond to the mean over 150 episode seeds.

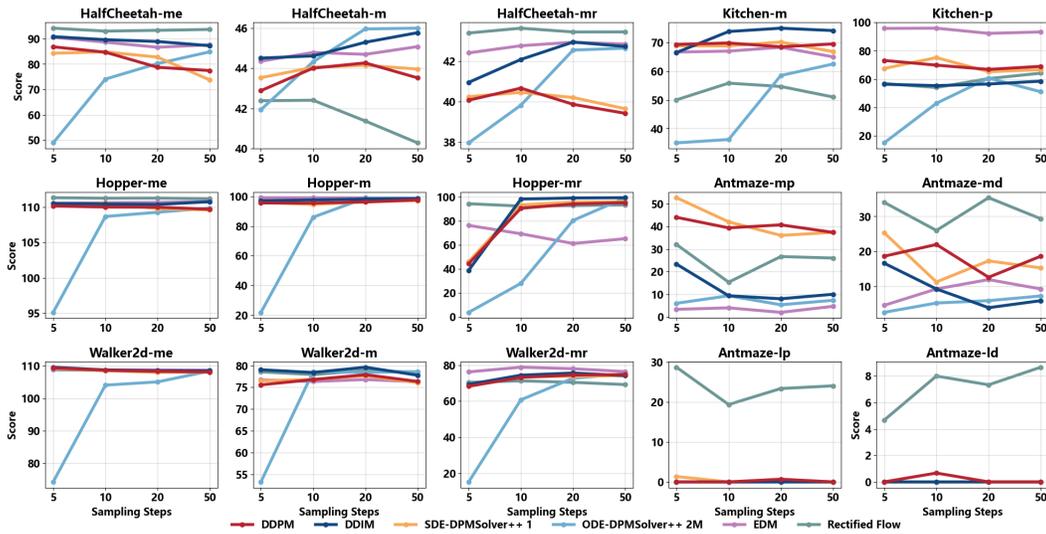

Figure 4: Full D4RL Results of DD. Performance of DD with various diffusion backbones and varying sampling steps. Results correspond to the mean over 150 episode seeds.

179 Due to space limitations in the main text, we present the full results of IDQL and DD on D4RL in
 180 Figure 3 and Figure 4. The algorithms are trained for 1×10^6 gradient steps, and the sampling steps for
 181 DD are set to 5, with other hyperparameters consistent with default settings. This experiment selects
 182 DDPM, DDIM, SDE-DPM-Solver++ 1, ODE-DPM-Solver++ (2M), EDM, and Rectified Flow as the
 183 diffusion/solver backbones. We select DDPM and DDIM because they are the first-order discretization
 184 of diffusion reverse SDE/ODE, respectively [47, 46]. We do not choose DPM-Solver because its
 185 first-order solver is equivalent to DDIM [34], and higher-order solvers may cause instability under
 186 guidance [35]. For DPM-Solver++, we select a first-order SDE solver, SDE-DPM-Solver++ 1,
 187 and a second-order ODE solver, ODE-DPM-Solver++ (2M). Since higher-order solvers can lead
 188 to instability, they are therefore not chosen. We select EDM and Rectified Flow because they have
 189 achieved excellent results in image generation but have not been widely used in the decision-making
 190 domain, to the best of our knowledge. Thanks to CleanDiffuser’s support for various solvers
 191 and varying sampling steps, the results for DDPM, DDIM, SDE-DPM-Solver++ 1, and ODE-DPM-
 192 Solver++ (2M) only require training one single model. Additionally, using different sampling steps
 193 does not require additional training. These features provide a great convenience for conducting
 194 ablation experiments. We believe these features of CleanDiffuser can also benefit future research
 195 efforts.

196 D.3 Additional Analyses of DMs in IL Benchmarks

197 Using the low-dim lift-ph task with 50 sample
 198 steps in Robomimic as a reference, we present
 199 the number of parameters and inference time for
 200 each variant of DiffusionPolicy, DiffusionBC,
 201 and ACT in table 3. Although Chi_UNet1d ex-
 202 hibits the best performance in many IL tasks,
 203 it has the largest model size and the slowest
 204 inference speed. Larger model size results in
 205 higher training costs, and in many real-world
 206 applications that require real-time inference, we
 207 need to make trade-offs between inference speed
 208 and performance. Compared to the transformer-
 209 based ACT algorithm, all structures of the dif-
 210 fusion policy exhibit slower sampling speeds
 211 because the denoising process requires multiple
 212 forwards for neural networks. This is also an
 213 important challenge that limits the application of DMs for decision-making. We also note that
 214 DiffusionBC is slower than DiffusionPolicy when using the same network architecture and model
 215 size, as DiffusionBC performs 8 additional steps of Diffusion-X sampling to mitigate OOD issues.
 216 Although the best-performing Chi_UNet1d model uses a considerable model size, simply increasing
 217 the Transformer-based DMs like DiT1d can sometimes harm performance. We discuss this in detail
 218 in appendix D.1, which is also consistent with the experimental observations of the [4]. Finding the
 219 optimal model size in applications remains an open research question.

Table 3: **The Model Size and Inference Time of DiffusionPolicy and DiffusionBC in Low-Dim Lift-ph.** DiffusionPolicy uses 50 sampling steps across the experiments, and DiffusionBC incorporates 8 additional Diffusion-X sampling steps.

| Algorithm | Model Size (M) | Inference Time (s) |
|-------------------------------|----------------|--------------------|
| DiffusionPolicy w/ Chi_UNet1d | 68.91 | 0.405 |
| DiffusionPolicy w/ Chi_TFM | 9.50 | 0.343 |
| DiffusionPolicy w/ DiT1d | 16.59 | 0.194 |
| DiffusionBC w/ DiT1d | 16.59 | 0.217 |
| DiffusionBC w/ Pearce_MLP | 0.83 | 0.062 |
| ACT | 7.83 | 0.006 |

220 E Experimental Details

221 E.1 Computing Resources

222 RL experiments are conducted on a server equipped with 2 Intel(R) Xeon(R) Gold 6326 CPUs @
 223 2.90GHz and 8 NVIDIA GeForce RTX3090 GPUs, and a server equipped with 2 Intel(R) Xeon(R)
 224 Gold 6326 CPUs @ 2.90GHz and 8 NVIDIA GeForce RTX2080Ti GPUs. IL experiments are
 225 conducted on a server equipped with 2 Intel(R) Xeon(R) Gold 6338 CPUs @ 2.00GHz and 8 NVIDIA
 226 A800 GPUs, and a server equipped with 2 Intel(R) Xeon(R) Gold 6338 CPUs @ 2.00GHz and 4
 227 NVIDIA GeForce RTX3090 GPUs.

228 **E.2 Evaluation Metrics**

229 In the D4RL benchmark, the scores are normalized to the range between 0 and 100 with expert-
 230 normalized scores = $100 \times \frac{\text{score} \times \text{random_score}}{\text{expert_score} - \text{random_score}}$ [9]. As for IL benchmarks, we report target area
 231 coverage as scores in the PushT benchmark and success rate in the Robomimic benchmark. In the
 232 Relay Kitchen environment, since the vast majority of human demonstrations can only complete
 233 4 subtasks, we denote the success rate of completing the i -th subtask as p_i and report the average
 234 success rate as score = $(p_1 + p_2 + p_3 + p_4)/4$.

235 **E.3 Algorithm Hyperparameters**

236 Unless stated otherwise, we utilize default hyperparameters from the official implementations for
 237 most algorithms and datasets. **Configuration files and hyperparameters for each algorithm and
 238 environment are available in YAML format on our GitHub repository for reproducibility.**

239 Key hyperparameters for each offline RL algorithm are presented in Table 4, and each offline IL
 240 algorithm in Table 5. We also reproduce the Transformer-based ACT [52] algorithm based on the
 241 official implementation, the key hyperparameters are in Table 50000.

Table 4: Hyperparameters for Diffusion Planners, Diffusion Policies and Diffusion Data Synthesizer for RL.

| Hyperparameter | Diffuser | DD | AdaptDiffuser | DQL | EDP | IDQL | SynthER |
|-----------------|----------------|----------------|----------------|---------|-------------------|----------|----------|
| Architecture | Janner_UNet | DiT | Janner_UNet | DQL_MLP | DQL_MLP | LNResnet | LNResnet |
| Diffusion Model | DDPM | DDIM | DDPM | DDPM | DPM-Solver++ (2M) | DDPM | DDIM |
| Sampling Steps | 20 | 20 | 20 | 5 | 15 | 5 | 128 |

242 **F Implemented Diffusion Models**

243 **F.1 DDPM/DDIM/DPM-Solver/DPM-Solver++**

244 **Applying Solvers with One Score Function.** Due to the generation processes of DDPM [19],
 245 DDIM [46], DPM-Solver [34], and DPM-Solver++ [35] can all be expressed using the same diffusion
 246 SDE/ODE [47], utilizing the same noise schedule, training just one noise predictor model enables the
 247 use of these four solvers for sampling. Recall that the diffusion ODE with noise prediction model is:

$$\frac{dx_t}{dt} = f(t)x_t + \frac{g^2(t)}{2\sigma_t} \epsilon_{\theta}(x_t, t). \tag{10}$$

Table 6: Hyperparameters for ACT in Low-Dim and Image Tasks.

| Hyperparameters | Value |
|-----------------------|---------------------------------|
| Learning Rate | 1e-5 |
| Batch Size | 256 (Low dim) / 64 (Image) |
| # Encoder Layers | 4 |
| # Decoder Layers | 7 |
| Feedforward Dimension | 256 |
| Hidden Dimension | 256 |
| # Heads | 8 |
| Chunk size | 16 |
| Beta | 10 |
| Gradient Steps | 1e6 |
| Control Mode | Vel (Kitchen) / Pos (Otherwise) |

248 Substituting $f(t) = \frac{d \log \alpha_t}{dt}$, $g^2(t) = \frac{d \sigma_t^2}{dt} - 2 \sigma_t^2 \frac{d \log \alpha_t}{dt}$, and conducting first-order discretization
 249 result in a recursive formula:

$$\mathbf{x}_t - \mathbf{x}_s = \frac{\alpha_t - \alpha_s}{\alpha_s} \mathbf{x}_s + \frac{1}{2 \sigma_s} \left[2 \sigma_s (\sigma_t - \sigma_s) - 2 \frac{\sigma_s^2}{\alpha_s} (\alpha_t - \alpha_s) \right] \epsilon_\theta(\mathbf{x}_s) \quad (11)$$

$$\mathbf{x}_t = \frac{\alpha_t}{\alpha_s} \mathbf{x}_s - \alpha_t \left(\frac{\sigma_s}{\alpha_s} - \frac{\sigma_t}{\alpha_t} \right) \epsilon_\theta(\mathbf{x}_s, s) \quad (12)$$

$$\mathbf{x}_t = \alpha_t \left(\frac{\mathbf{x}_t - \sigma_t \epsilon_\theta(\mathbf{x}_s, s)}{\alpha_s} \right) + \sqrt{\sigma_s^2} \epsilon_\theta(\mathbf{x}_s, s), \quad (13)$$

250 where t and s are the next and current sampling steps. Equation (13) is DDIM update [46]. By
 251 introduce $\beta_s = (\sigma_t / \sigma_s) \sqrt{1 - \alpha_s^2 / \alpha_t^2}$, the generative process of DDPM is:

$$\mathbf{x}_t = \alpha_t \left(\frac{\mathbf{x}_t - \sigma_t \epsilon_\theta(\mathbf{x}_s, s)}{\alpha_s} \right) + \sqrt{\sigma_s^2 - \beta_s^2} \epsilon_\theta(\mathbf{x}_s, s) + \beta_s \epsilon_s, \quad (14)$$

252 where $\epsilon_s \sim \mathcal{N}(\mathbf{0}, \mathbf{I})$ is standard Gaussian noise independent of \mathbf{x}_s . DPM-Solver leverages the
 253 semi-linearity of the diffusion ODE and formulates the exact solution by the ‘‘variation of constants’’
 254 formula:

$$\mathbf{x}_t = e^{\int_s^t f(\tau) d\tau} \mathbf{x}_s + \int_s^t \left(e^{\int_\tau^t f(r) dr} \frac{g^2(\tau)}{2 \sigma_\tau} \epsilon_\theta(\mathbf{x}_\tau, \tau) \right) d\tau \quad (15)$$

$$\mathbf{x}_t = \frac{\alpha_t}{\alpha_s} \mathbf{x}_s - \alpha_t \int_s^t \frac{d \lambda_\tau}{d \tau} \frac{\sigma_\tau}{\alpha_\tau} \epsilon_\theta(\mathbf{x}_\tau, \tau) d\tau, \quad (16)$$

255 where $\lambda_t := \log(\alpha_t / \sigma_t)$ is the log-signal-to-noise-ratio (log-SNR). This formulation eliminates the
 256 approximation error of the linear term since it is exactly computed, and the non-linear term can be
 257 approximated using its Talor expansion:

$$\mathbf{x}_t = \frac{\alpha_t}{\alpha_s} \mathbf{x}_s - \alpha_t \sum_{n=0}^{k-1} \epsilon_\theta^{(n)}(\mathbf{x}, s) \int_{\lambda_s}^{\lambda_t} e^{-\lambda} \frac{(\lambda - \lambda_s)^n}{n!} d\lambda + \mathcal{O}((\lambda_t - \lambda_s)^{k+1}). \quad (17)$$

258 In CleanDiffuser, we have implemented only *DPM-Solver-1*, corresponding to the $k=1$ scenario in
 259 Equation (17), as guided sampling tends to make high-order solvers unstable [35], leading to poor
 260 performance in decision-making tasks. DPM-Solver++ alleviates this instability issue by using a
 261 data prediction model $\mathbf{x}_\theta(\mathbf{x}_t, t)$ instead of the noise prediction model $\epsilon_\theta(\mathbf{x}_t, t)$, transforming the
 262 generative process into:

$$\mathbf{x}_t = \frac{\sigma_t}{\sigma_s} \mathbf{x}_s + \sigma_t \sum_{n=0}^{k-1} \mathbf{x}_\theta^{(n)}(\mathbf{x}, s) \int_{\lambda_s}^{\lambda_t} e^\lambda \frac{(\lambda - \lambda_s)^n}{n!} d\lambda + \mathcal{O}((\lambda_t - \lambda_s)^{k+1}), \quad (18)$$

263 where $\mathbf{x}_\theta(\mathbf{x}_t, t)$ is trained to predict the original data \mathbf{x}_0 from the perturbed data \mathbf{x}_s . In
 264 CleanDiffuser, we have implemented DPM-Solver++ for $k \leq 2$, as it already yields satisfac-
 265 tory results at $k = 2$, while higher-order solvers may still lead to instability.

266 Although the data prediction model can mitigate the instability issue caused by guided sampling and
 267 easily clip data to address the ‘‘train-test mismatch’’ problem [35], there is still no definitive evidence
 268 in practice to determine the superiority of either the data prediction model or the noise prediction
 269 model. In CleanDiffuser, we provide users with the option to choose between these two prediction
 270 models and use the approximation $\mathbf{x}_t \approx \alpha_t \mathbf{x}_\theta(\mathbf{x}_t, t) + \sigma \epsilon_\theta(\mathbf{x}_t, t)$ to seamlessly switch between the
 271 two formulations to cater to the requirements of different solvers.

272 **Noise Schedules.** CleanDiffuser provides two popular noise schedules by default: *Linear Noise*
 273 *Schedule* [19] and *Cosine Noise Schedule* [38]. The former defines:

$$\alpha_t = \exp\left(-\frac{(\beta_1 - \beta_0)}{4}t^2 - \frac{\beta_0}{2}t\right), \quad (19)$$

274 where $\beta_0 = 0.1$, $\beta_1 = 20$ and $\sigma_t = \sqrt{1 - \alpha_t^2}$. The diffusion SDE/ODE is solved between $[\epsilon, T]$,
 275 where $\epsilon = 0.001$ and $T = 1$ for numerical stability. The later schedule defines:

$$\alpha_t = \frac{\cos\left(\frac{\pi}{2} \cdot \frac{t+s}{1+s}\right)}{\cos\left(\frac{\pi}{2} \cdot \frac{s}{1+s}\right)} \quad (20)$$

276 where $s = 0.008$ and $\sigma_t = \sqrt{1 - \alpha_t^2}$. The diffusion SDE/ODE is solved between $[\epsilon, T]$, where
 277 $\epsilon = 0.001$ and $T = 0.9946$ for numerical stability. Beyond the two schedules, CleanDiffuser
 278 allows users to fully customize new noise schedules according to the specified format to explore
 279 algorithm performance.

280 F.2 EDM

281 EDM [23] rewrites the diffusion forward process in Equation (1) as:

$$\mathbf{x}_t = s_t(\mathbf{x}_0 + \sigma_t \epsilon_t), \quad (21)$$

282 which can be interpreted as adding noise to a scaled version of the original data. By setting the scale
 283 $s_t \equiv 1$ to a constant, EDM obtains the following reverse process:

$$\frac{d\mathbf{x}_t}{dt} = -\dot{\sigma}_t \sigma_t \nabla_{\mathbf{x}} \log p(\mathbf{x}; \sigma_t) dt, \quad (22)$$

284 where $p(\mathbf{x}; \sigma_t) = p_t(\mathbf{x})$. A data prediction model $D_\theta(\mathbf{x}; \sigma)$ is trained to approximate $\mathbf{x} +$
 285 $\sigma^2 \nabla_{\mathbf{x}} \log p(\mathbf{x}; \sigma)$ and results in a practical generative process:

$$\mathbf{x}_t = \mathbf{x}_s + (t - s) \cdot \left(\frac{\dot{\sigma}_s}{\sigma_s} \mathbf{x}_s - \frac{\dot{\sigma}_s}{\sigma_s} D_\theta(\mathbf{x}_s; \sigma_s) \right). \quad (23)$$

286 One feature of EDM is that it applies preconditioning to D_θ :

$$D_\theta(\mathbf{x}; \sigma) = c_{\text{skip}}(\sigma) \mathbf{x} + c_{\text{out}}(\sigma) F_\theta(c_{\text{in}}(\sigma) \mathbf{x}; c_{\text{noise}}(\sigma)). \quad (24)$$

287 where F_θ is the neural network to be trained, c_{skip} modulates the skip connection, c_{in} and c_{out} scale
 288 the input and output magnitudes, and c_{noise} maps noise level σ into a conditioning input for F_θ . F_θ is
 289 trained by minimizing the noising score matching loss:

$$\mathcal{L}(\theta; \sigma) = \mathbb{E}_{\mathbf{y} \sim p_{\text{data}}, \mathbf{n} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I})} [\lambda(\sigma) \|D_\theta(\mathbf{y} + \mathbf{n}; \sigma) - \mathbf{y}\|_2^2], \quad (25)$$

290 where $\lambda(\sigma)$ is the loss weight. These coefficients are optimized to achieve the following objectives:
 291 (1) inputs of F_θ have unit variance, (2) training target of F_θ have unit variance, (3) c_{skip} can minimize
 292 c_{out} so that the errors of F_θ are amplified as little as possible, and (4) the loss of F_θ has a uniform
 293 weight across noise levels. The optimization results give the following design choices: $c_{\text{skip}} =$
 294 $\sigma_{\text{data}}^2 / (\sigma^2 + \sigma_{\text{data}}^2)$, $c_{\text{out}} = \sigma \cdot \sigma_{\text{data}} / \sqrt{\sigma_{\text{data}}^2 + \sigma^2}$, $c_{\text{in}} = 1 / \sqrt{\sigma_{\text{data}}^2 + \sigma^2}$, $c_{\text{noise}} = \log(\sigma) / 4$, and
 295 $\lambda(\sigma) = (\sigma_{\text{data}}^2 + \sigma^2) / (\sigma_{\text{data}} \cdot \sigma)^2$.

296 **Noise Schedule.** CleanDiffuser provides only one default noise schedule, which is specially
 297 designed for EDM:

$$\sigma_t = t, \quad t \in [\sigma_{\text{min}}, \sigma_{\text{max}}], \quad (26)$$

298 where $\sigma_{\text{min}} = 0.002$ and $\sigma_{\text{max}} = 80$.

299 **F.3 Rectified Flow**

300 Rectified flow [33] is an ODE on time $t \in [0, 1]$:

$$\frac{d\mathbf{x}_t}{dt} = \mathbf{v}_\theta(\mathbf{x}_t, t), \quad (27)$$

301 where the drift force \mathbf{v}_θ is trained to drive the flow to follow the direction $(\mathbf{x}_0 - \mathbf{x}_1)$ of the linear path
 302 pointing from \mathbf{x}_1 to \mathbf{x}_0 as much as possible, by solving a simple least squares regression problem:

$$\mathcal{L}(\theta) = \mathbb{E}_{\mathbf{x}_0 \sim p_0, \mathbf{x}_1 \sim p_1, t \sim \text{Uniform}(0,1)} \left[\left\| (\mathbf{x}_0 - \mathbf{x}_1) - \mathbf{v}_\theta(\mathbf{x}_t, t) \right\|_2^2 \right], \quad (28)$$

303 where $\mathbf{x}_t = t\mathbf{x}_1 + (1-t)\mathbf{x}_0$. It achieves the mutual transformation of samples from two distributions
 304 p_0 and p_1 , by solving Equation (26) forward or backward. Rectified flow possesses many favorable
 305 properties that allow it to continuously learn from its own sampled data to straighten the ODE flow,
 306 and this procedure is called *reflow*. The straighter the ODE flow, the fewer sampling steps are needed
 307 to achieve good generation quality. In an ideal scenario, if the flow becomes completely straight, then
 308 we have:

$$\mathbf{x}_t = t\mathbf{x}_1 + (1-t)\mathbf{x}_0 = \mathbf{x}_1 + (1-t)\mathbf{v}(\mathbf{x}_1, 1), \quad \forall t \in [0, 1], \quad (29)$$

309 which enables one-step sampling. The Rectified Flow implemented in `CleanDiffuser` has full
 310 functionality to transform samples from any two arbitrary probability distributions. By default, it
 311 follows the settings in diffusion models, where p_0 is the dataset distribution and p_1 is the standard
 312 Gaussian distribution.

313 **G Implemented Algorithms**

314 **G.1 Diffusion Planners**

315 **Diffuser.** [21] Diffuser is the first diffusion planning algorithm, and its paradigm has been widely
 316 adopted in subsequent diffusion planning algorithms. Diffuser generates state-action pair trajectories
 317 $\mathbf{x} = [x^\tau, \dots, x^{\tau+H-1}]$ from:

$$p(\mathbf{x} | \mathcal{O}^{\tau:\mathcal{T}}) \propto p(\mathbf{x}) p(\mathcal{O}^{\tau:\mathcal{T}} | \mathbf{x}) = p(\mathbf{x}) \prod_{t=\tau}^{\mathcal{T}} \exp(r(s^t, a^t)), \quad (30)$$

318 where $\mathcal{O}^{t_1:t_2}$ is a binary random variable denoting the optimality of a trajectory from t_1 to t_2 , and \mathcal{T}
 319 is the episode terminal time step of the trajectory². Therefore, it is natural to define the classifier in
 320 CG as a reward function on perturbed trajectories:

$$\nabla_{\mathbf{x}} \log p_t(\mathbf{x}_t | \mathcal{O}^{\tau:\mathcal{T}}) = \nabla_{\mathbf{x}} \log p_t(\mathbf{x}_t) + \sum_{k=\tau}^{\mathcal{T}} \nabla_{s_t^k, a_t^k} r(s_t^k, a_t^k) = \nabla_{\mathbf{x}} \log p_t(\mathbf{x}_t) + \nabla_{\mathbf{x}} \mathcal{J}_\phi(\mathbf{x}_t, t), \quad (31)$$

321 where $\mathcal{J}_\phi(\mathbf{x}_t, t)$ is a neural network trained to predict the episodic cumulative reward $\sum_{k=\tau}^{\mathcal{T}} r(s_t^k, a_t^k)$
 322 of the perturbed trajectory \mathbf{x}_t . At each inference step, given the current state s^k , Diffuser sets
 323 and freezes the first state of the trajectory as s^k and performs guided sampling in an inpainting
 324 manner to generate a set of trajectories $\{\mathbf{x}_0\}$. Subsequently, it identifies the optimal trajectory
 325 $\mathbf{x}_0^* = \arg \max_{\mathbf{x}_0} \mathcal{J}_\phi(\mathbf{x}_0, 0)$ that maximizes the episodic cumulative reward, and extracts the first
 326 action a^k in \mathbf{x}_0^* to execute.

327 **Decision Diffuser.** [1] Decision Diffuser (DD) introduces another prominent framework that utilizes a
 328 state-only trajectory formulation and implements CFG by discarding the optimality variable $\mathcal{O}^{\tau:\mathcal{T}}$ in
 329 favor of directly employing normalized episodic cumulative reward $y = \sum_{t=\tau}^{\mathcal{T}} r(\mathbf{x})$ as the condition.
 330 As no additional reward predictor can be used for trajectory selection, DD generates only a single

²In previous works, authors typically consider only the trajectory cumulative reward as the generative condition, i.e. using $\mathcal{O}^{\tau:\tau+H-1}$, which overlooks future optimality. Their code implementations actually use the episodic cumulative reward, i.e. $\mathcal{O}^{\tau:\mathcal{T}}$. Therefore, we adopt this episodic cumulative reward expression.

331 trajectory at each inference step and employs an trained inverse dynamic model \mathcal{I}_ϕ to predict the
 332 action to be executed $a^t = \mathcal{I}_\phi(s^t, s^{t+1})$.

333 **AdaptDiffuser.** [31] Observing that the insufficient diversity of offline RL training data may limit the
 334 sample quality of DMs, AdaptDiffuser, an extension of Diffuser, proposes to utilize self-generated
 335 diverse synthetic expert data to fine-tune itself. The pipeline of AdaptDiffuser involves initially
 336 training a Diffuser as usual, then generating a large amount of synthetic expert data and using a
 337 discriminator to filter out high-quality data. Finally, fine-tuning is done on this dataset. This self-
 338 evolving process can be repeated multiple times to optimize the model, and different directions of
 339 model self-evolution can be controlled by designing different discriminators. The inference method
 340 of AdaptDiffuser is consistent with Diffuser, and its performance for seen tasks has been enhanced
 341 while also being able to adapt to unseen tasks.

342 G.2 Diffusion Polices

343 **Diffusion Q-Learning.** [50] Diffusion Q-learning (DQL) leverages the capability of DMs to model
 344 complex distributions, directly applying DDPM as the policy $\pi_\theta(\mathbf{a}_0|s)$ in the RL actor-critic frame-
 345 work. Sampling from the policy is therefore equivalent to the denoising process of the diffusion
 346 model. The Bellman operator can be used to train the Q-value function of the diffusion policy:

$$\mathcal{L}(\phi) = \mathbb{E}_{(s^k, \mathbf{a}^k, r, s^{k+1}) \sim \mathcal{D}, \mathbf{a}_0^{k+1} \sim \pi_{\phi'}} \left[\left\| \left(r + \gamma \min_{i=1,2} Q_{\phi'_i}(s^{k+1}, \mathbf{a}_0^{k+1}) \right) - Q_{\phi_i}(s^k, \mathbf{a}^k) \right\|_2^2 \right], \quad (32)$$

347 where ϕ_1 and ϕ_2 represent the parameters of the double Q-learning trick, ϕ' and θ' represent the target
 348 networks. For policy optimization, DQL employs the most basic form of Offline RL optimization,
 349 which involves training the policy to maximize the Q-value while imitating behavior policies, using a
 350 weighting factor α to balance the influence of both aspects:

$$\mathcal{L}(\theta) = \mathcal{L}_{\text{score}}(\theta) - \alpha \cdot \mathbb{E}_{\mathbf{s} \sim \mathcal{D}, \mathbf{a}_0 \sim \pi_\theta} [Q_\phi(\mathbf{s}, \mathbf{a}_0)], \quad (33)$$

351 where $\mathcal{L}_{\text{score}}(\theta)$ is the score matching loss used for diffusion model training. As the scale of the
 352 Q-value function varies in different offline datasets, to normalize it, DQL sets $\alpha = \frac{\eta}{\mathbb{E}_{(s, \mathbf{a}) \sim \mathcal{D}} [Q_\phi(s, \mathbf{a})]}$
 353 and tunes η for loss term balance. The Q_ϕ in the denominator is only for normalization and not
 354 differentiated over.

355 **Efficient Diffusion Policy.** [22] Efficient Diffusion Policy (EDP) aims to address the significant
 356 computational overhead caused by iterative sampling and gradient computation during the training
 357 of the DQL. Compared to DQL, EDP proposes using DPM-Solver instead of DDPM to reduce the
 358 number of sampling steps. Then, EDP introduces an *action approximation* technique, where during
 359 policy optimization, one-step denoising is performed on the perturbed action \mathbf{a}_t to approximate \mathbf{a}_0 .
 360 For the process using a data prediction model \mathbf{x}_θ and a noise prediction model ϵ_θ separately, the
 361 following two equations can express the technique:

$$\mathbf{a}_0 \approx \mathbf{x}_\theta(\mathbf{a}_t, t) \quad (34)$$

$$\mathbf{a}_0 \approx \frac{\mathbf{a}_t - \sigma_t \epsilon_\theta(\mathbf{a}_t, t)}{\alpha_t}. \quad (35)$$

362 EDP reduces the sampling steps to 15 (even though DQL has only 5 sampling steps) and performs
 363 only one-step denoising during policy optimization, significantly speeding up the model training
 364 process and achieving performance close to that of DQL.

365 **Implicit Diffusion Q-Learning.** [16] Implicit Diffusion Q-Learning (IDQL) models the policy from
 366 the perspective of general *constrained policy search* (CPS), in which the optimal policy is described
 367 as a weighted behavior policy:

$$\pi^*(\mathbf{a}|s) = \pi_\theta^b(\mathbf{a}|s) w(\mathbf{a}|s), \quad s.t. \int_{\mathcal{A}} w(\mathbf{a}|s) d\mathbf{a} = 1, \quad \forall s, \quad (36)$$

368 where $\pi_\theta^b(\mathbf{a}|s)$ represents the behavior policy learned by the diffusion model from the dataset,
 369 and $w(\mathbf{s}, \mathbf{a})$ is a weight function. IDQL derives its weight function from the generalized implicit

370 Q-learning:

$$w(\mathbf{a}|\mathbf{s}) = \frac{|f'(Q_\phi(\mathbf{s}, \mathbf{a}) - V^*(\mathbf{s}))|}{|Q_\phi(\mathbf{s}, \mathbf{a}) - V^*(\mathbf{s})|}, \quad (37)$$

371 where f can be any convex function, $f' = \frac{\partial f}{\partial V(\mathbf{s})}$, and

$$V^*(\mathbf{s}) = \arg \min_{V(\mathbf{s})} \mathbb{E}_{\mathbf{a} \sim \pi_\theta^b(\mathbf{a}|\mathbf{s})} [f(Q_\phi(\mathbf{s}, \mathbf{a}) - V(\mathbf{s}))]. \quad (38)$$

372 Therefore, the training of IDQL consists of two independent processes: training the diffusion model
 373 to clone the behavior policy and training the IQL-based weight function $w(\mathbf{a}|\mathbf{s})$. At each inference
 374 step, IDQL samples a set of candidate actions $\{\mathbf{a}_0\}$, computes the weights $\{w(\mathbf{s}, \mathbf{a}_0)\}$, and then
 375 selects the action to be executed as a categorical from $\{w(\mathbf{s}, \mathbf{a}_0)\}$.

376 **DiffusionBC.** [40] DiffusionBC constructs an observation-to-action diffusion model for imitating
 377 stochastic and multimodal human demonstrations. The basic version of DiffusionBC applies diffusion
 378 generation directly as a diffusion policy $\pi(\mathbf{a}_0|\mathbf{s}, \mathbf{a}_t, t)$ with noisy action $\mathbf{a}_t \in \mathbb{R}^{|\mathbf{a}|}$, denoising timestep
 379 t and observation \mathbf{s} (possibly with a history) input. To better select intra-distributional actions to
 380 mimic human behavior, DiffusionBC proposed the **Diffusion-X Sampling** trick, which encourages
 381 higher likelihood actions during sampling. For diffusion-X sampling, the sampling process first
 382 runs normal T denoising timesteps, and timesteps is fixed to $t = 1$, then extra denoising iterations
 383 continue to run for M timesteps toward higher-likelihood regions.

384 **DiffusionPolicy.** [4] Similar to DiffusionBC, Diffusion Policy also uses a diffusion model to directly
 385 approximate the conditional distribution $p(\mathbf{a}|\mathbf{s})$, but uses two key design choices: (1) **Closed-loop**
 386 **Action-chunking Prediction:** Diffusion Policy generates sequences of actions per prediction rather
 387 than single action to encourage temporal consistency and smoothness in long-term planning to better
 388 fit multimodal distributions. At time step t , the policy takes the latest T_s (the observation horizon)
 389 steps of observation data \mathbf{s}_t as input and predicts H steps of actions, of which T_a (the action prediction
 390 horizon) steps of actions are executed on the robot without re-planning. (2) **Network Architecture**
 391 **Options:** Diffusion Policy adopts the traditional 1D-Unet [21] and DiT [41] to new CNN-based Unet
 392 and time-series diffusion transformer network architectures. CNN-based Diffusion Policy conditions
 393 the action generation process on observation \mathbf{s} with Feature-wise Linear Modulation (FiLM) [42] and
 394 Transformer-based Diffusion Policy fuses state \mathbf{s} and action \mathbf{a} features via cross attention to jointly
 395 predict $\epsilon_\theta(o, a_k, k)$, where k is sinusoidal embedding for diffusion iteration. The Diffusion Policy
 396 has demonstrated excellent performance and high stability in multiple simulation environments and
 397 real-world tasks for imitation learning and is a widely used baseline for embodied AI.

398 G.3 Diffusion Data Synthesizers.

399 **SynthER.** [36] SynthER uses the diffusion model to generate one-step transitions $(\mathbf{s}, \mathbf{a}, r, d, \mathbf{s}')$.
 400 Trained on an offline dataset, SynthER then upsamples it to a larger dataset (in D4RL, SynthER
 401 upsamples each dataset to 5M transitions), which helps other offline RL algorithms to optimize the
 402 agent policy.

403 H Limitations, Challenges, and Future Directions

404 **Limitations.** Although the modular structure and pipeline design of CleanDiffuser greatly simplify
 405 the implementation difficulty for researchers deploying DMs, the inherent complexity of the principles
 406 and improvements of DMs still requires a considerable amount of time to deeply understand each type
 407 of module. We hope to alleviate this issue and better facilitate collaboration through comprehensive
 408 configuration files and documentation, as well as active maintenance and updates. Additionally,
 409 When dealing with certain specific issues, CleanDiffuser may require tailored adjustments and
 410 optimizations. For instance, the current version of CleanDiffuser does not directly support
 411 discrete or hybrid action space tasks, which may be mitigated through techniques such as action
 412 representation [28] or using categorical diffusion models [6].

413 Based on experimental analyses of CleanDiffuser, we have identified several promising areas for
414 further research as follows:

415 **Unleashing the potential of diffusion planners.** Analogous to the classification of RL algorithms,
416 as diffusion planners can imaginatively generate interactive trajectories, they should be categorized
417 under model-based RL (MBRL). In MBRL, there are various ways to utilize learned dynamic
418 models, including planning to search for the optimal action [13, 17], optimizing policies using
419 rollout trajectories [12], and even combining these two approaches [15, 14]. Currently, diffusion
420 planners are limited to the first paradigm, and due to their sensitivity to guidance and lack of safety
421 constraints, they are prone to OOD plans [7], falling short in performance compared to other offline
422 MBRL algorithms. Future research can explore new paradigms for diffusion planners, attempting
423 diverse ways to utilize generated trajectories or integrating safety constraints to enhance the fidelity
424 of generated trajectories, thereby unleashing the full potential of diffusion planners.

425 **Exploring the reasons behind sampling degradation.** In ??, we discuss an anomaly known as
426 *sampling degradation*, where the algorithm’s performance decreases as the number of sampling steps
427 increases. This anomaly has been identified in previous works [22, 3] and remains an open question.
428 Theoretically, more sampling steps should result in a more accurate SDE/ODE solution, ultimately
429 producing higher-fidelity samples. This naturally prompts a trade-off exploration between sampling
430 steps and performance during implementation. However, in experiments, increasing sampling steps
431 in certain tasks does not improve performance and can even lead to a decrease. Future research can
432 systematically investigate this anomaly to provide optimal recommendations for selecting sampling
433 steps.

434 **Understanding the impact of SDE and ODE.** In our experiments, we observe consistent differences
435 in SDE solvers and ODE solvers on algorithm performance, tendency to sampling degradation, and
436 sensitivity to guidance. While there is existing research on the impact of SDE and ODE in computer
437 vision [39, 35], there is still a gap in research within the decision-making domain. Future research
438 can fill this gap and explore the implications of SDE and ODE solvers in decision-making tasks.

439 **Accelerating Diffusion Model Sampling.** Due to the denoising process involved in iterative sampling,
440 DMs face the issue of slow sampling speeds when used for decision-making. This poses significant
441 challenges in scenarios such as real-time robot control or game AI. DiffuserLite [7] is a diffusion
442 planner method that addresses this issue by modeling the diffusion process through a plan refinement
443 process for coarse-to-fine-grained trajectory generation and further accelerates the sampling speed
444 using rectified flow. Further speeding up the sampling speed of various roles of DMs remains a
445 promising research direction.

446 I Potential Social Impact

447 CleanDiffuser fills a critical gap in the current landscape by providing a unified and modularized
448 framework that empowers researchers and practitioners to explore new frontiers. This will accelerate
449 the development and deployment of diffusion-based decision-making applications, such as various
450 robotics research and products. However, CleanDiffuser may also be used in military weapon
451 development.
