A Preliminary Knowledge

Definition 5. For a convex function $h : \mathbb{R}^{d_q} \rightarrow \mathbb{R}$ whose domain is $\mathcal{Q} \subseteq \mathbb{R}^{d_q}$, the Legendre conjugate of $h^* : \mathcal{Q}^* \rightarrow \mathbb{R}$ is defined as:

$$h^*(y) := \sup_{q' \in \mathcal{Q}} \{\langle q', q \rangle - h(q')\} = - \inf_{q' \in \mathcal{Q}} \{-\langle q', q \rangle + h(q')\},$$

$$\forall q \in \mathcal{Q}^* := \{q \in \mathbb{R}^{d_q} : \sup_{q' \in \mathcal{Q}} \{\langle q', q \rangle - g(q')\} < \infty\}.$$

Remark 1. When h is strongly convex in \mathbb{R}^{d_q} , it is lower bounded and therefore $\mathcal{Q}^* = \mathbb{R}^{d_y}$.

Definition 6. The function $h : \mathbb{R}^{d_q} \rightarrow \mathbb{R}$ is called closed if its epigraph on its domain \mathcal{Q} is closed.

Lemma 4. Suppose $h : \mathbb{R}^{d_y} \rightarrow \mathbb{R}$ is $l_{h,1}$ -smooth and α_h -strongly convex and its domain $\mathcal{Q} \subseteq \mathbb{R}^{d_q}$ is convex, closed and non-empty.

1. If additionally $\mathcal{Q} = \mathbb{R}^{d_q}$, the gradient mappings ∇h and ∇h^* are inverse of each other ([53]); and $h^* : \mathbb{R}^{d_q} \rightarrow \mathbb{R}$ is $\frac{1}{\alpha_h}$ -smooth and $\frac{1}{l_{h,1}}$ -strongly convex (Proposition 2.6 [31]).

2. If $\mathcal{Q} \subset \mathbb{R}^{d_q}$, h^* is $\frac{1}{\alpha_h}$ -smooth ([34]) and convex (Theorem 4.43 [30]).

Lemma 5. Suppose $h : \mathbb{R}^{d_q} \rightarrow \mathbb{R}$ is strongly convex on domain convex, closed and non-empty \mathcal{Q} , $h^c : \mathbb{R}^{d_q} \rightarrow \mathbb{R}^{d_c}$ is convex in q and d_c is finite, and $\{q \in \mathcal{Q} : h^c(q) \leq 0\}$ is non-empty.

1. The problem $\min_{q \in \{q \in \mathcal{Q} : h^c(q) \leq 0\}} h(q)$ has a unique feasible solution.

563 2. When linear independence constraint qualification (LICQ) condition additionally
 564 holds for g^c , the corresponding Lagrange multiplier, i.e. solution to the problem
 565 $\max_{\mu \in \mathbb{R}^{d_c}} \min_{q \in \mathcal{Q}} h(y) + \langle \mu, h^c(q) \rangle$ is unique [65].

566 **Lemma 6** (Lemma 3.1 in [8]; Lemma 2.11 in [54]). Suppose $\mathcal{Q} \subseteq \mathbb{R}^{d_q}$ is convex, closed, and
 567 nonempty. For any $q_1 \in \mathbb{R}^{d_q}$ and any $q_2 \in \mathcal{Q}$,

$$\langle \text{Proj}_{\mathcal{Q}}(q_1) - q_2, \text{Proj}_{\mathcal{Q}}(q_1) - q_1 \rangle \leq 0. \quad (20)$$

568 In this way, take $q_1 = q_3 - \eta g$ for any $q_3 \in \mathcal{Q}$, and denote $q_3^+ = \text{Proj}_{\mathcal{Q}}(q_3 - \eta g)$,

$$\langle g, q_3^+ - q_2 \rangle \leq -\frac{1}{\eta} \langle q_3^+ - q_2, q_3^+ - q_3 \rangle. \quad (21)$$

569 **Lemma 7** (Theorem 3.10 [8]). Suppose a differentiable function h is $l_{h,1}$ -smooth and $\alpha_{h,2}$ -strongly
 570 convex. Consider the constrained problem $\min_{q \in \mathcal{Q}} h(q)$ where \mathcal{Q} is non-empty, closed and convex.
 571 Projected Gradient Descent with $\eta \leq \frac{1}{l_{h,1}}$ converges linearly to the unique $q^* = \arg \min_{q \in \mathcal{Q}} h(q)$:

$$\| \text{Proj}_{\mathcal{Q}}(q^t - \eta \nabla h(q^t)) - q^* \| \leq (1 - \alpha \eta)^{1/2} \|q^t - q^*\| \leq (1 - \alpha \eta / 2) \|q^t - q^*\|. \quad (22)$$

572 B Analysis of the Penalty-Based Lagrangian Reformulation

573 B.1 Proof of Lemma 1

574 *Proof.* According to Lemma 5, for any fixed x , there exist a unique $\mu_g^*(x)$ such that the primal
 575 problem is $g(x, y) + \langle \mu_g^*(x), g^c(x, y) \rangle$. This problem is α_g -strongly convex with respect to y . This
 576 α_g is independent from x and therefore the quadratic growth in statement 1 can be concluded
 577 following Theorem 2 in [35].

578 As g is strongly convex and continuous, and $\mathcal{Y}(x)$ is a closed set, there exists a unique solution $y_g^*(x)$
 579 such that $g(x, y_g^*(x)) = v(x)$. If $y \neq y_g^*(x)$ and $y \in \mathcal{Y}(x)$, $g(x, y) > v(x)$, which completes the
 580 proof of statement 2. \square

581 B.2 Proof of Theorem 1

582 *Proof.* We know from Lemma 1 that $g(x, y) - v(x) \geq \|y - y_g^*(x)\|^2$ and $g(x, y) = v(x)$ if and only
 583 if $y = y_g^*(x)$. This is a squared-distance bound following Definition 1 in [57]. Under Lipschitzness
 584 of $f(x, y)$ with respect to y , the ϵ -approximate problem is equivalent to its penalty reformulation

$$\min_{(x, y) \in \{\mathcal{X} \times \mathcal{Y} : g^c(x, y) \leq 0\}} f(x, y) + \gamma(g(x, y) - v(x)) \quad (23)$$

585 with $\gamma = o(\epsilon^{-0.5})$ following Theorems 1 and 2 in [57]. This is in equivalence to

$$\min_{x \in \mathcal{X}} \min_{y \in \mathcal{Y}(x)} f(x, y) + \gamma(g(x, y) - v(x)). \quad (24)$$

586 Suppose $(x_0, y_0) \in \{\mathcal{X} \times \mathcal{Y} : g^c(x, y) \leq 0\}$ being a solution to (23). Suppose for any $x \in \mathcal{X}$,
 587 $y_F^*(x) \in \arg \min_{y \in \mathcal{Y}(x)} f(x, y) + \gamma(g(x, y) - v(x))$. We know that for any $x \in \mathcal{X}$, $y \in \mathcal{Y}(x)$,

$$\begin{aligned} f(x_0, y_0) + \gamma(g(x_0, y_0) - v(x_0)) &\leq f(x, y_F^*(x)) + \gamma(g(x, y_F^*(x)) - v(x)) \\ &\leq f(x, y) + \gamma(g(x, y) - v(x)). \end{aligned}$$

588 This means any solution to (23) is a solution to (24). On the other hand, suppose $x_0 \in \mathcal{X}$, $y_F^*(x_0) \in$
 589 $\mathcal{Y}(x_0)$ is a solution to (24). We know that for any $(x, y) \in \{\mathcal{X} \times \mathcal{Y} : g^c(x, y) \leq 0\}$,

$$\begin{aligned} f(x_0, y_F^*(x_0)) + \gamma(g(x_0, y_F^*(x_0)) - v(x_0)) &\leq f(x, y_F^*(x)) + \gamma(g(x, y_F^*(x)) - v(x)) \\ &\leq f(x, y) + \gamma(g(x, y) - v(x)). \end{aligned}$$

590 This means any solution to (24) is a solution to (23).

591 Besides, we know $f(x, y)$ is $l_{f,1}$ -smooth, $g(x, y)$ is α_g -strongly convex in y , by the definitions, we
 592 know $f(x, y) + \gamma(g(x, y) - v(x))$ is $(\gamma \alpha_g - l_{f,1})$ -strongly convex in y as

$$f(x, y_1) + \gamma(g(x, y_1) - v(x)) - f(x, y_2) + \gamma(g(x, y_2) - v(x))$$

$$\begin{aligned}
&= f(x, y_1) - f(x, y_2) + \gamma(g(x, y_1) - g(x, y_2)) \\
&\geq \langle \nabla_y f(x, y_2), y_1 - y_2 \rangle - \frac{l_{f,1}}{2} \|y_1 - y_2\|^2 + \gamma \langle \nabla_y g(x, y_2), y_1 - y_2 \rangle + \gamma \frac{\alpha_g}{2} \|y_1 - y_2\|^2 \\
&= \langle \nabla_y f(x, y_2) + \gamma \nabla_y g(x, y_2), y_1 - y_2 \rangle + \frac{\gamma \alpha_g - l_{f,1}}{2} \|y_1 - y_2\|^2.
\end{aligned} \tag{25}$$

593 Moreover, according to Assumption 2 the constraint $g^c(x, y)$ is convex in y , and $\min_{y \in \mathcal{Y}(x)} f(x, y) +$
594 $\gamma(g(x, y) - v(x))$ is equivalent to its equivalent *Lagrangian Dual Form*

$$\max_{\mu \in \mathbb{R}_+^{d_c}} \min_{y \in \mathcal{Y}} f(x, y) + \gamma(g(x, y) - v(x)) + \langle \mu, g^c(x, y) \rangle \tag{26}$$

595 according to the Lagrangian Duality theory, as in Chapter 4 in [54]. Therefore, (23) can be recovered
596 to (2a) and this completes the proof. \square

597 C Analysis of the Differentiability of Value Functions

598 **Lemma 8** (Theorem 2.16 in [30]). *Suppose $h(x, y)$ is strongly convex in y and is Lipschitz with*
599 *respect to x , $h^c(x, y)$ is convex in y and is Lipschitz with respect to x , and both \mathcal{Y} and $\{y \in \mathcal{Y} :$
600 $h^c(x, y) \leq 0\}$ are non-empty, closed, and convex. For the problem $\min_{y \in \{y \in \mathcal{Y} : h^c(x, y) \leq 0\}} h(x, y)$,*
601 *the unique solution $y_h^*(x)$ and unique Lagrange multiplier $\mu_h^*(x)$, defined as*

$$(y_h^*(x), \mu_h^*(x)) := \arg \max_{\mu \in \mathbb{R}_+^{d_x}} \min_{y \in \mathcal{Y}} h(x, y) + \langle \mu, h^c(x, y) \rangle, \tag{27}$$

602 is Lipschitz in x . In other words, there exist $L_h \geq 0$ that, for all $x_1, x_2 \in \mathcal{X}$,

$$\|(y_h^*(x_1); \mu_h^*(x_1)) - (y_h^*(x_2); \mu_h^*(x_2))\| \leq L_h \|x_1 - x_2\|.$$

603 **Remark 2.** *This also implies the L_h -continuity of both $y^*(x)$ and $\mu^*(x)$.*

604 **Remark 3.** *When $h(x, y) = g(y)$, and $h^c(x, y) = A^\top y - x$, the Lipschitzness of both $y^*(x)$ and*
605 *$\mu^*(x)$ in x holds automatically.*

606 **Lemma 9** (Theorem 4.24 in [6]). *Consider the value function for the constrained problem*

$$v_h(x) = \min_{y \in \mathcal{Y}} h_0(x, y) \quad \text{s.t.} \quad h_i(x, y) \leq 0, \quad i = 1, \dots, I, \tag{P_x}$$

607 where \mathcal{Y} is convex, closed, and non-empty. Denote $(S(x), \Lambda(x))$ as the solution sets for y and the
608 Lagrange multipliers (μ_1, \dots, μ_I) :

$$(S(x), \Lambda(x)) := \arg \min_y \max_{(\mu_1, \dots, \mu_I) \geq 0} h_0(x, y) + \sum_{i=1}^I \mu_i h_i(x, y).$$

609 *If the following conditions hold:*

- 610 1. $h_0(x, \cdot)$ is convex and the solution set $S(x)$ is non-empty.
- 611 2. The directional regularity condition in a direction d , holds for all $y \in S(x)$.
- 612 3. For a sequence $t_n \rightarrow 0$, define the sequence $x_n := x + t_n d + O(t_n)$. If (P_{x_n}) is attained by
613 an $O(t_n)$ -optimal solution sequence y_n with a limit point (in the strong topology) $y \in S(x)$.

614 Then $v_h(x)$ is Hadamard directionally differentiable at x in the direction d , and the directional
615 derivative can be written as

$$v_h'(x, d) = \inf_{y \in S(x)} \sup_{(\mu_1, \dots, \mu_I) \in \Lambda(x)} \nabla_x \left(h_0(x, y) + \sum_{i=1}^I \mu_i h_i(x, y) \right).$$

616 **Remark 4.** *When $y_h^*, \mu_h^* = (\mu_{h,1}^*, \dots, \mu_{h,I}^*)$ are unique in $S(x)$ and $\Lambda(x)$, we have:*

$$v_h'(x, d) = \nabla_x \left(h_0(x, y^*) + \sum_{i=1}^I \mu_i^* h_i(x, y^*) \right).$$

617 Before proving Lemma 2 and 3, we would like to introduce a more general form.

618 **Lemma 10.** Suppose \mathcal{Y} and $\{y \in \mathcal{Y} : h^c(x, y) \leq 0\}$ are both non-empty, closed and convex, $h(x, y)$
619 is jointly smooth and strongly convex in y , $h^c(x, y)$ is convex in y , and both $h(x, y)$ and $h^c(x, y)$ are
620 Lipschitz with respect to x .

$$v_h(x) = \min_{y \in \mathcal{Y}} h(x, y) \quad \text{s.t.} \quad h^c(x, y) \leq 0$$

621 is differentiable with

$$\nabla v_h(x) = \nabla_x h(x, y_h^*(x)) + \langle \mu_h^*(x), h^c(x, y_h^*(x)) \rangle,$$

622 where $(y_h^*(x), \mu_h^*(x))$ defined in (27) are unique.

623 *Proof.* As $h(x, y)$ being strongly convex in y , condition 1 in Lemma 9 is satisfied and the solution
624 sets are of singleton value $(y_h^*(x), \mu_h^*(x))$ according to Lemma 5. Moreover, the smoothness of
625 $f(x, y)$ guarantees Robinson's constraint qualification [2], which implies the directional regularity
626 condition for any direction d (Theorem 4.9. (ii) in [6]). Additionally, under the Lipschitzness of
627 $h(x, y)$ and $h^c(x, y)$ with respect to x , $y_h^*(x), \mu_h^*(x)$ are Lipschitz according to Lemma 8. This
628 guarantees Condition 2 in Lemma 9 can be satisfied for all directions d . Condition 3 is a direct
629 outcome from Lemma 8. This completes the proof. \square

630 C.1 Proof of Lemma 2

631 *Proof.* The problem $\min_{y \in \mathcal{Y}} g(x, y)$ s.t. $g^c(x, y) \leq 0$ fits in the setting of Lemma 10 by taking
632 $h(x, y) = g(x, y)$ and $h^c(x, y) = g^c(x, y)$. Therefore the derivative (8) can be obtained accordingly.
633 Moreover, for any $x_1, x_2 \in \mathcal{X}$,

$$\begin{aligned} & \|\nabla v(x_1) - \nabla v(x_2)\| \\ &= \|\nabla_x g(x_1, y_g^*(x_1)) + \langle \mu_g^*(x_1), \nabla_x g^c(x_1, y_g^*(x_1)) \rangle - \nabla_x g(x_2, y_g^*(x_2)) \\ & \quad - \langle \mu_g^*(x_2), \nabla_x g^c(x_2, y_g^*(x_2)) \rangle\| \\ &\stackrel{(a)}{\leq} \|\nabla_x g(x_1, y_g^*(x_1)) - \nabla_x g(x_2, y_g^*(x_2))\| \\ & \quad + \|\langle \mu_g^*(x_1), \nabla_x g^c(x_1, y_g^*(x_1)) \rangle - \langle \mu_g^*(x_1), \nabla_x g^c(x_2, y_g^*(x_2)) \rangle\| \\ & \quad + \|\langle \mu_g^*(x_1), \nabla_x g^c(x_2, y_g^*(x_2)) \rangle - \langle \mu_g^*(x_2), \nabla_x g^c(x_2, y_g^*(x_2)) \rangle\| \\ &\stackrel{(b)}{\leq} (l_{g,1} + B_g l_{g^c,1})(\|x_1 - x_2\| + \|y_g^*(x_1) - y_g^*(x_2)\|) + l_{g^c,0} \|\mu_g^*(x_1) - \mu_g^*(x_2)\| \\ &\stackrel{(c)}{\leq} ((l_{g,1} + B_g l_{g^c,1})(1 + L_g) + l_{g^c,0} L_g) \|x_1 - x_2\|, \end{aligned}$$

634 where (a) follows triangle inequality; (b) leverage on the Lipschitzness of ∇g , g^c and ∇g^c , and
635 the upper bound for $\|\mu_g^*(x)\|$; and (c) uses the Lipschitzness of $y_g^*(x)$ and $\mu_g^*(x)$. As the bound
636 is loose due to the use of triangle inequality, we can conclude that $v(x)$ is $l_{v,1}$ -smooth where
637 $l_{v,1} \leq ((1 + B_g)(1 + L_g)l_{g^c,1} + l_{g^c,0}L_g)$. \square

638 C.2 Proof of Lemma 3

639 *Proof.* As $\gamma > \frac{l_{f,1}}{\alpha_g}$, we know $f(x, y) + \gamma(g(x, y) - v(x))$ is $(\gamma\alpha_g - l_{f,1})$ -strongly convex by (25).
640 By strong duality,

$$\begin{aligned} F_\gamma(x) &= \min_{y \in \mathcal{Y}} f(x, y) + \gamma(g(x, y) - v(x)) \\ &\quad \text{s.t.} \quad g^c(x, y) \leq 0. \end{aligned}$$

641 Considering the smoothness of $v(x)$ as presented in Lemma 2, all assumptions in Lemma 10 are
642 satisfied. Therefore the derivative (9) can be obtained. For any $x_1, x_2 \in \mathcal{X}$,

$$\begin{aligned} & \|\nabla F(x_1) - \nabla F(x_2)\| \\ &= \|\nabla_x f(x_1, y_F^*(x_1)) + \gamma(\nabla_x g(x_1, y_F^*(x_1)) - \nabla v(x_1)) + \langle \mu_F^*(x_1), \nabla_x g^c(x_1, y_F^*(x_1)) \rangle \\ & \quad - \nabla_x f(x_2, y_F^*(x_2)) - \gamma(\nabla_x g(x_2, y_F^*(x_2)) - \nabla v(x_2)) - \langle \mu_F^*(x_2), \nabla_x g^c(x_2, y_F^*(x_2)) \rangle\| \end{aligned}$$

$$\begin{aligned}
&\stackrel{(a)}{\leq} \|\nabla_x f(x_1, y_F^*(x_1)) - \nabla_x f(x_2, y_F^*(x_2))\| + \gamma \|\nabla_x g(x_1, y_F^*(x_1)) - \nabla_x g(x_2, y_F^*(x_2))\| \\
&\quad + \gamma \|\nabla v(x_1) - \nabla v(x_2)\| + \|\langle \mu_F^*(x_1), \nabla_x g^c(x_1, y_F^*(x_1)) \rangle - \langle \mu_F^*(x_1), \nabla_x g^c(x_2, y_F^*(x_2)) \rangle \| \\
&\quad + \|\langle \mu_F^*(x_1), \nabla_x g^c(x_2, y_F^*(x_2)) \rangle - \langle \mu_F^*(x_2), \nabla_x g^c(x_2, y_F^*(x_2)) \rangle \| \\
&\stackrel{(b)}{\leq} (l_{f,1} + \gamma l_{g,1} + B_F l_{g^c,1}) (\|x_1 - x_2\| + \|y_F^*(x_1) - y_F^*(x_2)\|) + \gamma l_{v,1} \|x_1 - x_2\| \\
&\quad + l_{g^c,0} \|\mu_F^*(x_1) - \mu_F^*(x_2)\| \\
&\stackrel{(c)}{\leq} ((l_{f,1} + \gamma l_{g,1} + B_F l_{g^c,1})(1 + L_F) + \gamma l_{v,1} + l_{f^c,0} L_F) \|x_1 - x_2\|,
\end{aligned}$$

643 where (a) follows triangle inequality; (b) leverage on the Lipschitzness of ∇f , ∇g , g^c and ∇g^c ,
644 and the upper bound for $\|\mu_F^*(x)\|$; and (c) uses the Lipschitzness of $y_F^*(x)$ and $\mu_F^*(x)$. As the
645 bound is loose due to the use of triangle equality, we can conclude that $F(x)$ is $l_{F,1}$ -smooth where
646 $l_{F,1} \leq (l_{f,1} + \gamma l_{g,1} + B_F l_{g^c,1})(1 + L_F) + \gamma l_{v,1} + l_{f^c,0} L_F$. \square

647 D Convergence Analysis of the Main Result

648 D.1 Proof of Theorem 12

649 Define the bias term $b(x_t)$ as

$$\begin{aligned}
b(x_t) &:= \nabla F(x_t) - g_t \\
&= (\nabla_x f(x_t, y_F^*(x_t)) + \gamma (\nabla_x g(x_t, y_F^*(x_t)) + \nabla v(x_t)) + \langle \mu_F^*(x_t), \nabla_x g^c(x_t, y_F^*(x_t)) \rangle) \\
&\quad - \left(\nabla_x f(x_t, y_{F,t}^{T_F}) + \gamma \left(\nabla_x g(x_t, y_{F,t}^{T_F}) - \nabla_x g(x_t, y_{g,t}^{T_g}) + \mu_{g,t}^{T_g} \right) + \langle \mu_{F,t}^{T_F}, \nabla_x g^c(x_t, y_{F,t}^{T_F}) \rangle \right).
\end{aligned}$$

650 In this way,

$$\begin{aligned}
\|b(x_t)\| &\stackrel{(a)}{\leq} \|\nabla_x f(x_t, y_{F,t}^{T_F}) - \nabla_x f(x_t, y_F^*(x_t))\| \\
&\quad + \gamma \left(\|\nabla_x g(x_t, y_{F,t}^{T_F}) - \nabla_x g(x_t, y_F^*(x_t))\| + \|\nabla_x g(x_t, y_{g,t}^{T_g}) - \nabla_x g(x_t, y_g^*(x_t))\| + \|\mu_{g,t}^{T_g} - \mu_g^*(x_t)\| \right) \\
&\quad + \|\langle \mu_{F,t}^{T_F}, \nabla_x g^c(x_t, y_{F,t}^{T_F}) \rangle - \langle \mu_F^*(x_t), \nabla_x g^c(x_t, y_{F,t}^{T_F}) \rangle \| \\
&\quad + \|\langle \mu_F^*(x_t), \nabla_x g^c(x_t, y_{F,t}^{T_F}) \rangle - \langle \mu_F^*(x_t), \nabla_x g^c(x_t, y_F^*(x_t)) \rangle \| \\
&\stackrel{(b)}{\leq} l_{f,1} \|y_{F,t}^{T_F} - y_F^*(x_t)\| + \gamma (l_{g,1} \|y_{F,t}^{T_F} - y_F^*(x_t)\| + l_{g,1} \|y_{g,t}^{T_g} - y_g^*(x_t)\| + \|\mu_{g,t}^{T_g} - \mu_g^*(x_t)\|) \\
&\quad + l_{g^c,0} \|\mu_{F,t}^{T_F} - \mu_F^*(x_t)\| + B_F l_{g^c,1} \|y_{F,t}^{T_F} - y_F^*(x_t)\| \\
&\stackrel{(c)}{=} (l_{f,1} + \gamma l_{g,1} + B_F l_{g^c,1}) \|y_{F,t}^{T_F} - y_F^*(x_t)\| + l_{g^c,0} \|\mu_{F,t}^{T_F} - \mu_F^*(x_t)\| \\
&\quad + \gamma \left(l_{g,1} \|y_{g,t}^{T_g} - y_g^*(x_t)\| + \|\mu_{g,t}^{T_g} - \mu_g^*(x_t)\| \right),
\end{aligned}$$

651 where (a) uses triangle inequality, (b) relies on Assumption 2 and Cauchy-Schwartz inequality, and
652 (c) is by rearrangement. Furthermore, according to Young's inequality,

$$\begin{aligned}
\|b(x_t)\|^2 &\leq 2 \left((l_{f,1} + \gamma l_{g,1} + B_F l_{g^c,1}) \|y_{F,t}^{T_F} - y_F^*(x_t)\| + l_{g^c,0} \|\mu_{F,t}^{T_F} - \mu_F^*(x_t)\| \right)^2 \\
&\quad + 2\gamma^2 \left(l_{g,1} \|y_{g,t}^{T_g} - y_g^*(x_t)\| + \|\mu_{g,t}^{T_g} - \mu_g^*(x_t)\| \right)^2 \\
&= O(\gamma^2 \epsilon_F + \gamma^2 \epsilon_g).
\end{aligned}$$

653 According to Lemma 3, $F_\gamma(x)$ is $l_{F,1}$ -smooth in \mathcal{X} . The projection guarantees that x_{t+1} and x_t are
654 in \mathcal{X} . In this way,

$$\begin{aligned}
F(x_{t+1}) &\leq F(x_t) + \langle \nabla F(x_t), x_{t+1} - x_t \rangle + \frac{l_{F,1}}{2} \|x_{t+1} - x_t\|^2 \\
&\leq F(x_t) + \langle g_t, x_{t+1} - x_t \rangle + \frac{1}{2\eta} \|x_{t+1} - x_t\|^2 + \langle b(x_t), x_{t+1} - x_t \rangle, \quad (28)
\end{aligned}$$

655 where the second inequality is by $\eta \leq \frac{1}{L_{F,1}}$.

656 Following lemma 6, we know that

$$\langle g_t, x_{t+1} - x_t \rangle \leq -\frac{1}{\eta} \|x_{t+1} - x_t\|^2.$$

657 Plugging this back to (28),

$$\begin{aligned} F(x_{t+1}) &\leq F(x_t) - \frac{1}{2\eta} \|x_{t+1} - x_t\|^2 + \langle b(x_t), x_{t+1} - x_t \rangle \\ &\leq F(x_t) - \frac{1}{2\eta} \|x_{t+1} - x_t\|^2 + \eta \|b(x_t)\|^2 + \frac{1}{4\eta} \|x_{t+1} - x_t\|^2 \\ &= F(x_t) - \frac{1}{4\eta} \|x_{t+1} - x_t\|^2 + \eta \|b(x_t)\|^2, \end{aligned}$$

658 where the second inequality is from Young's inequality. Telescoping therefore gives

$$\begin{aligned} \frac{1}{T} \sum_{t=0}^{T-1} \|G_\eta(x_t)\|^2 &\leq \frac{4}{\eta T} (F(x_0) - F(x_T)) + \frac{4}{T} \sum_{t=0}^{T-1} \|b(x_t)\|^2 \\ &= O(\eta^{-1} T^{-1}) + O(\gamma^2 \epsilon_F + \gamma^2 \epsilon_g) \\ &= O(\gamma T^{-1} + \gamma^2 \epsilon_F + \gamma^2 \epsilon_g) \end{aligned}$$

659 where last equality comes from $\eta = O(\gamma^{-1})$. This completes the proof.

660 D.2 Proof of Theorem 3

661 In Algorithm 2, with T_y being sufficiently large, we are implementing an accelerated projected
662 gradient descent on $-D(\mu)$. The following lemma presents the convergence analysis of such an
663 accelerated method on smooth and convex functions.

664 **Lemma 11.** *Suppose $h(\cdot)$ is $l_{h,1}$ -smooth, and there exist a unique $q^* = \arg \min_{q \in \mathcal{Q}} h(q)$. Consider
665 the constrained problem $\min_{q \in \mathcal{Q}} h(q)$ where \mathcal{Q} is non-empty, closed and convex. Accelerated
666 projected gradient descent algorithm as in (29) and (30) with step size $\eta \leq \frac{1}{l_{h,1}}$, initial value
667 $q_0 = q_{-1}$,*

$$q_{t+\frac{1}{2}} = q_t + \frac{t-1}{t+2} (q_t - q_{t-1}) \quad (29)$$

$$q_{t+1} = \text{Proj}_{\mathcal{Q}}(q_{t+\frac{1}{2}} - \eta \nabla h(q_{t+\frac{1}{2}})) \quad (30)$$

668 for $t = 0, \dots, T-1$ will lead to

$$h(q_T) - h(q^*) < \frac{2}{\eta(T+1)^2} \|q_0 - q^*\|^2.$$

669 *Proof.* Denote $\theta_t = \frac{2}{t+1}$, and

$$u_t = q_{t-1} + \frac{1}{\theta_t} (q_t - q_{t-1}).$$

670 (29) can be reformulated as

$$q_{t+\frac{1}{2}} = (1 - \theta_{t+1})q_t + \theta_{t+1}u_t.$$

671 In this way, we have

$$\begin{aligned} &h(q_{t+1}) - h(q^*) - (1 - \theta_{t+1})(h(q_t) - h(q^*)) \\ &= h(q_{t+1}) - (\theta_{t+1}h(q^*) + (1 - \theta_{t+1})h(q_t)) \\ &\stackrel{(a)}{\leq} h(q_{t+1}) - h(\theta_{t+1}q^* + (1 - \theta_{t+1})q_t) \\ &= h(q_{t+1}) - h(q_{t+\frac{1}{2}}) + h(q_{t+\frac{1}{2}}) - h(\theta_{t+1}q^* + (1 - \theta_{t+1})q_t) \end{aligned}$$

$$\begin{aligned}
&\stackrel{(b)}{\leq} \langle \nabla h(q_{t+\frac{1}{2}}), q_{t+1} - q_{t+\frac{1}{2}} \rangle + \frac{1}{2\eta} \|q_{t+1} - q_{t+\frac{1}{2}}\|^2 + \langle \nabla h(q_{t+\frac{1}{2}}), q_{t+\frac{1}{2}} - (\theta_{t+1}q^* + (1 - \theta_{t+1})q_t) \rangle \\
&= \langle \nabla h(q_{t+\frac{1}{2}}), q_{t+1} - (\theta_{t+1}q^* + (1 - \theta_{t+1})q_t) \rangle + \frac{1}{2\eta} \|q_{t+1} - q_{t+\frac{1}{2}}\|^2 \\
&\stackrel{(c)}{\leq} -\frac{1}{\eta} \langle q_{t+1} - (\theta_{t+1}q^* + (1 - \theta_{t+1})q_t), q_{t+1} - q_{t+\frac{1}{2}} \rangle + \frac{1}{2\eta} \|q_{t+1} - q_{t+\frac{1}{2}}\|^2 \\
&= -\frac{1}{\eta} \langle \theta_{t+1}u_{t+1} - \theta_{t+1}\mu^*, \theta_{t+1}u_{t+1} - \theta_{t+1}u_t \rangle + \frac{1}{2\eta} \|\theta_{t+1}u_{t+1} - \theta_{t+1}u_t\|^2 \\
&= \frac{\theta_{t+1}^2}{2\eta} (\|u_t - q^*\|^2 - \|u_{t+1} - q^*\|^2),
\end{aligned}$$

672 where (a) follows the convexity of h ; (b) is by the smoothness of h and $\eta \leq \frac{1}{l_{h,1}}$, and the convexity
673 of h ; and (c) follows from Lemma 6 as $\theta_{t+1}q^* + (1 - \theta_{t+1})q_t$ is a linear combination of $q_t, q^* \in \mathcal{Q}$
674 and is in \mathcal{Q} .

675 Rearranging gives

$$\begin{aligned}
\frac{\eta}{\theta_{t+1}^2} (h(q_{t+1}) - h(q^*)) + \frac{1}{2} \|u_{t+1} - q^*\|^2 &\leq (1 - \theta_{t+1}) \frac{\eta}{\theta_{t+1}^2} (h(q_t) - h(q^*)) + \frac{1}{2} \|u_t - q^*\|^2 \\
&\stackrel{(d)}{\leq} \frac{\eta}{\theta_t^2} (h(q_t) - h(q^*)) + \frac{1}{2} \|u_t - q^*\|^2 \\
&\stackrel{(e)}{\leq} \frac{\eta}{\theta_1^2} (h(q_1) - h(q^*)) + \frac{1}{2} \|u_1 - q^*\|^2 \\
&\stackrel{(f)}{\leq} \frac{(1 - \theta_1)\eta}{\theta_1^2} (h(q_0) - h(q^*)) + \frac{1}{2} \|u_0 - q^*\|^2 = \|u_0 - q^*\|^2
\end{aligned}$$

676 where (d) is from $\frac{1 - \theta_{t+1}}{\theta_{t+1}^2} \leq \frac{1}{\theta_t}$, (e) is the outcome of iteration, and (f) again uses the first inequality.
677 Additionally, as $u_0 = q_0$, rearranging gives

$$h(q_T) - h(q^*) < \frac{2}{\eta(T+1)^2} \|q_0 - q^*\|^2. \quad (31)$$

678 This completes the proof. \square

679 In this way, we are ready to proceed to the **proof of Theorem 3**

680 *Proof.* To restate, for a fixed x , define

$$\begin{aligned}
L_g(\mu, y) &= g(x, y) + \langle \mu, g^c(x, y) \rangle, \\
L_F(\mu, y) &= f(x, y) + \gamma(g(x, y) - v(x)) + \langle \mu, g^c(x, y) \rangle,
\end{aligned}$$

681 and

$$\begin{aligned}
D_g(\mu) &:= \min_{y \in \mathcal{Y}} L_g(\mu, y), \\
D_F(\mu) &:= \min_{y \in \mathcal{Y}} L_F(\mu, y).
\end{aligned}$$

682 D_g and D_F are concave in μ according to Lemma 2.58 in [54]. Moreover, $L_g(\mu, y)$ is α_g -strongly
683 convex and $(l_{g,1} + l_{g^c,1})$ -smooth in y and $L_F(\mu, y)$ is $(\gamma\alpha_g - l_{f,1})$ -strongly convex and $(l_{f,1} + \gamma l_{g,1} +$
684 $l_{g^c,1})$ -smooth in y . Therefore,

$$\begin{aligned}
y_g^*(\mu; x) &:= \arg \min_{y \in \mathcal{Y}} L_g(\mu, y), \\
y_F^*(\mu; x) &:= \arg \min_{y \in \mathcal{Y}} L_F(\mu, y)
\end{aligned}$$

685 are respectively $\frac{1}{\alpha_g}$ and $\frac{1}{\gamma\alpha_g - l_{f,1}}$ -Lipschitz to μ (Theorem F.10 in [16]; Theorem 4.47 in [30]). In
 686 this way, following Lemma 9, we have

$$\begin{aligned}\nabla D_g(\mu) &= \nabla_{\mu} L_g(\mu, y_g^*(\mu; x)) = g^c(x, y_g^*(\mu; x)), \\ \nabla D_F(\mu) &= \nabla_{\mu} L_F(\mu, y_F^*(\mu; x)) = g^c(x, y_F^*(\mu; x)).\end{aligned}$$

687 Additionally, g^c is $l_{g^c,0}$ -Lipschitz by Assumption 1, in this way, for any $\mu_1, \mu_2 \in \mathbb{R}_+^{d_c}$:

$$\begin{aligned}\|\nabla D_g(\mu_1) - \nabla D_g(\mu_2)\| &= \|g^c(x, y_g^*(\mu_1; x)) - g^c(x, y_g^*(\mu_2; x))\| \\ &\leq l_{g^c,0} \|y_g^*(\mu_1; x) - y_g^*(\mu_2; x)\| \leq \frac{l_{g^c,0}}{\alpha_g} \|\mu_1 - \mu_2\|.\end{aligned}\quad (32)$$

688 and

$$\begin{aligned}\|\nabla D_F(\mu_1) - \nabla D_F(\mu_2)\| &= \|g^c(x, y_F^*(\mu_1; x)) - g^c(x, y_F^*(\mu_2; x))\| \\ &\leq l_{g^c,0} \|y_F^*(\mu_1; x) - y_F^*(\mu_2; x)\| \leq \frac{l_{g^c,0}}{\gamma\alpha_g - l_{f,1}} \|\mu_1 - \mu_2\|.\end{aligned}\quad (33)$$

689 We can conclude that D_g and D_F are respectively $\frac{l_{g^c,0}}{\alpha_g}$ and $\frac{l_{g^c,0}}{\gamma\alpha_g - l_{f,1}}$ -smooth.

690 Fixing $\mu_{t+\frac{1}{2}}$, steps 4-7 are T_y -step projected gradient descent on y with step size $\eta_{g,1} \leq \frac{1}{l_{g,1} + l_{g^c,1}}$
 691 and $\eta_{F,1} \leq \frac{1}{l_{f,1} + \gamma l_{g,1} + l_{g^c,1}}$ respectively for the two problems to have linear convergence according
 692 to Lemma 7. For $T_y = O(\log(\epsilon_g^{-1}))$, we know $\|y_{t+1} - y_g^*(\mu_{t+\frac{1}{2}}; x)\| = O(\epsilon_g)$ to solve (7). For
 693 $T_y = O(\log(\epsilon_F^{-1}))$, we know $\|y_{t+1} - y_F^*(\mu_{t+\frac{1}{2}}; x)\| = O(\epsilon_F)$ to solve (5).

694 The algorithm is, therefore, an accelerated projected gradient descent method on $-D_g(\mu)$ and
 695 $-D_F(\mu)$, both of which are convex and smooth. By Lemma 11, we can conclude the complexity is
 696 $\tilde{O}(\epsilon_g^{-0.5})$ for conducting on (7) to achieve

$$D_g(\mu_g^*(x)) - D_g(\mu_{T_g}) < \epsilon_g, \quad (34)$$

697 and similarly, the complexity is $\tilde{O}(\epsilon_F^{-0.5})$ for conducting on (5) to achieve

$$D_F(\mu_F^*(x)) - D_F(\mu_{T_F}) < \epsilon_F. \quad (35)$$

698 Moreover, the problems

$$\max_{\mu \in \mathbb{R}_+^{d_c}} D_g(\mu) \quad \text{and} \quad \max_{\mu \in \mathbb{R}_+^{d_c}} D_F(\mu)$$

699 are respectively equivalent to the respective unconstrained problems with the Lagrange multipliers

$$\max_{\mu \in \mathbb{R}^{d_c}} \tilde{D}_g(\mu) := D_g(\mu) + \lambda_g^\top \mu \quad \text{and} \quad \max_{\mu \in \mathbb{R}^{d_c}} \tilde{D}_F(\mu) := D_F(\mu) + \lambda_F^\top \mu$$

700 for some λ_g, λ_F being non-negative and finite in all dimension, i.e. $0 \leq \lambda_g < \infty, 0 \leq \lambda_F < \infty$, and

$$\lambda_g^\top \mu_g^*(x) = 0 \quad \text{and} \quad \lambda_F^\top \mu_F^*(x) = 0, \quad (36)$$

701 as $D_g(\mu)$ and $D_F(\mu)$ are both concave in μ and $\mu \in \mathbb{R}_+^{d_c}$ is equivalent to $\mu \geq 0$. These properties
 702 are well-known, see details in Chapter 4 in [54]. The first-order stationary condition requires
 703 $\nabla \tilde{D}_g(\mu_g^*(x)) = \nabla D_g(\mu_g^*(x)) + \lambda_g = 0$ and $\nabla \tilde{D}_F(\mu_F^*(x)) = \nabla D_F(\mu_F^*(x)) + \lambda_F = 0$ and
 704 therefore

$$\nabla D_g(\mu_g^*(x)) = -\lambda_g \quad \text{and} \quad \nabla D_F(\mu_F^*(x)) = -\lambda_F. \quad (37)$$

705 In this way, for all $\mu \in \mathcal{B}(\mu_g^*(x); \delta_g) \cap \mathbb{R}_+^{d_c}$.

$$\begin{aligned}D_g(\mu_g^*(x)) - D_g(\mu) &= \int_{\tau=0}^1 \langle \nabla D_g(\mu + \tau(\mu_g^*(x) - \mu)), \mu_g^*(x) - \mu \rangle d\tau \\ &= \int_{\tau=0}^1 \frac{1}{\tau} \langle \nabla D_g(\mu_g^*(x)) - D_g(\mu + \tau(\mu_g^*(x) - \mu)), \tau(\mu - \mu_g^*(x)) \rangle d\tau\end{aligned}$$

$$\begin{aligned}
& - \langle \nabla D_g(\mu_g^*(x)), \mu - \mu_g^*(x) \rangle \\
& \stackrel{(a)}{\geq} \int_0^1 C_{\delta_g} \|\mu - \mu_g^*(x)\|^2 \tau d\tau - \langle \nabla D_g(\mu_g^*(x)), \mu - \mu_g^*(x) \rangle \\
& \stackrel{(b)}{=} \frac{C_{\delta_g}}{2} \|\mu - \mu_g^*(x)\|^2 + \langle \lambda_g, \mu - \mu_g^*(x) \rangle \\
& \stackrel{(c)}{\geq} \frac{C_{\delta_g}}{2} \|\mu - \mu_g^*(x)\|^2,
\end{aligned}$$

706 where (a) uses (15) and the fact that the $\mu, \mu_g^*(x) \in \mathcal{B}(\mu_g^*(x); \delta_g) \cap \mathbb{R}_+^{d_c}$ implies $\mu + \tau(\mu_g^*(x) - \mu) \in$
707 $\mathcal{B}(\mu_g^*(x); \delta_g) \cap \mathbb{R}_+^{d_c}$; (b) solves the integral and $\lambda_g = -\nabla D_g(\mu_g^*(x))$; and (c) follows from the fact
708 that $\langle \lambda, \mu_g^*(x) \rangle = 0$ by the nature of the Lagrangian reformulated objective (Chapter 4 in [54]) and
709 $\mu, \lambda_g \geq 0$.

710 Analogously, for all $\mu \in \mathcal{B}(\mu_F^*(x); \delta_F) \cap \mathbb{R}_+^{d_c}$,

$$D_F(\mu_F^*(x)) - D_F(\mu) \geq \frac{C_{\delta_F}}{2} \|\mu - \mu_F^*(x)\|^2.$$

711 In this way, for all $\epsilon_g < \frac{C_{\delta_g}}{2} \delta_g$, when it achieves (34) with complexity $\tilde{O}(\epsilon_g^{-0.5})$ to solve (7),

$$\begin{aligned}
& \|\mu_{T_g} - \mu_g^*(x)\|^2 = O(\epsilon_g), \\
& \text{and } \|y_{T_g} - y_g^*(x)\|^2 \leq \|y_{T_g} - y_g^*(\mu_{T_g}; x)\|^2 + \|\mu_{T_g} - \mu_g^*(x)\|^2 \\
& \leq (1/\alpha_g + 1) \|\mu_{T_g} - \mu_g^*(x)\|^2 = O(\epsilon_g).
\end{aligned}$$

712 Similarly, for (5), for all $\epsilon_g < \frac{C_{\delta_g}}{2} \delta_g$, the complexity to achieve (35) and

$$\begin{aligned}
& \|\mu_{T_F} - \mu_F^*(x)\|^2 = O(\epsilon_F), \\
& \text{and } \|y_{T_F} - y_F^*(x)\|^2 \leq \|y_{T_F} - y_F^*(\mu_{T_F}; x)\|^2 + \|\mu_{T_F} - \mu_F^*(x)\|^2 \\
& \leq (1/\alpha_F + 1) \|\mu_{T_F} - \mu_F^*(x)\|^2 = O(\epsilon_F)
\end{aligned}$$

713 is $\tilde{O}(\epsilon_F^{-0.5})$. This completes the proof. \square

714 D.3 Proof of Theorem 4

715 In this section, we consider

$$g^c(x, y) = g_1^c(x)^\top y - g_2^c(x) \quad (38)$$

716 being affine in y , and $\mathcal{Y} = \mathbb{R}^{d_y}$.

717 Therefore, for fixed x , take (7) and (5) as $L(\mu, y)$ both fit into a special case of *strongly-convex-*
718 *concave saddle point problems* in the following form:

$$\max_{\mu \in \mathbb{R}_+^{d_c}} \min_{y \in \mathbb{R}^{d_y}} -h_1(\mu) + y^\top A \mu + h_2(y). \quad (39)$$

719 For (7), $A = g_1^c(x)$, $h_1(\mu) = g_2^c(x)^\top \mu$ is convex (linear) in μ , and $h_2(y) = g(x, y)$ is α_g -strongly
720 convex in y . For (5), $A = g_1^c(x)$, $h_1(\mu) = g_2^c(x)^\top \mu$ is convex (linear) in μ , $h_2(y) = g(x, y)$ is
721 $\gamma\alpha_g - l_{f,1}$ -strongly convex in y .

722 In this way, we would like to show the effectiveness of the single-loop algorithm, Algorithm 2 without
723 acceleration and $T_y = 1$, on the problems in (39), which is a general form to (7) and (5). In other
724 words, we are going to prove Theorem 7, which is a more general theorem to Theorem 4.

725 **Theorem 7.** *Suppose $L(\mu, y)$ is in the form of (39) where A is full rank in column, h_1 is concave and*
726 *$l_{h_1,1}$ -smooth, h_2 is α_{h_2} -strongly convex and $l_{h_2,1}$ -smooth satisfying $l_{h_1,1} = O(1)$, $l_{h_2,1}, l_{\alpha_2} \geq O(1)$,*
727 *and $\frac{l_{h_2,1}}{\alpha_{h_2}} = O(1)$. Conduct Algorithm 2 without acceleration, $T_y = 1$, $\eta_1 = O(\frac{1}{l_{h_2,1}}) \leq \frac{1}{l_{h_2,1}}$, $\eta_2 =$*

728 *$O(\epsilon) \leq \frac{1}{l_{h_1,1} + \sigma_{\max}^2(A)/\alpha_{h_2}}$ for arbitrary small positive $\epsilon \leq \left(\frac{4l_{h_2,1}\sigma_{\max}(A)}{\alpha_{h_2}\sigma_{\min}^2(A)}(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}})\right)^{-1}$,*
729 *yields output (μ_T, y_T) such that*

$$\|\mu_t - \mu^*\|^2 < \epsilon, \quad \text{and} \quad \|y_t - y^*\|^2 < \epsilon$$

730 *with complexity $O(\log(\epsilon^{-1}))$. Here, $(\mu^*, y^*) = \arg \max_{\mu \in \mathbb{R}^{d_c}} \min_{y \in \mathbb{R}^{d_y}} L(\mu, y)$.*

731 **Remark 5.** It emphasizes on $l_{h_1,1} = O(1)$, $l_{h_2,1}, l_{\alpha_2} \geq O(1)$, and $\frac{l_{h_2,1}}{\alpha_{h_2}} = O(1)$ as $l_{h_2,1}, l_{\alpha_2} \propto \gamma$
 732 when taking (5) as $L(\mu, y)$.

733 Before proceeding, we would first look at $D(\mu)$ as (18) and conclude its smoothness and strong
 734 concavity as in the following Lemma.

735 **Lemma 12.** Suppose h_1 is concave and $l_{h_1,1}$ -smooth, h_2 is α_{h_2} -strongly convex and $l_{h_2,1}$ -smooth,
 736 and A is full column rank. In this way, $D(\mu)$ defined in (18) equals

$$D(\mu) = -h_1(\mu) - h_2^*(-A\mu),$$

737 and is $\frac{\sigma_{\min}^2(A)}{l_{h_2,1}}$ -strongly concave and $(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}})$ -smooth with respect to μ .

738 *Proof.* Following Definition 5, we have

$$D(\mu) = -h_1(\mu) - h_2^*(-A\mu)$$

739 where h_2^* is $\frac{1}{l_{h_2,1}}$ -strongly convex and $\frac{1}{\alpha_{h_2}}$ -smooth according to Lemma 4.

740 For all μ_1, μ_2 ,

$$\begin{aligned} -D(\mu_1) - (-D(\mu_2)) &= h_2^*(-A\mu_1) - h_2^*(-A\mu_2) + h_1(\mu_1) - h_1(\mu_2) \\ &\geq \left\langle \frac{\partial h_2^*(-A\mu_2)}{\partial -A\mu_2}, -A\mu_1 + A\mu_2 \right\rangle + \frac{1/l_{h_2,1}}{2} \|A\mu_1 - A\mu_2\|^2 + \langle \nabla h_1(\mu_2), \mu_1 - \mu_2 \rangle \\ &\geq \langle \nabla D(\mu_2), \mu_1 - \mu_2 \rangle + \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}} \|\mu_1 - \mu_2\|^2. \end{aligned}$$

741 where the first inequality follows the strong convexity of h_2^* and the fact that $-h_1$ is convex as h_1 is
 742 concave. and the second inequality follows the chain rule to formulate $\nabla D(\mu_2)$. Therefore, $-D(\mu)$
 743 is $\frac{\sigma_{\min}^2(A)}{l_{h_2,1}}$ -strongly convex, and $D(\mu)$ is $\frac{\sigma_{\min}^2(A)}{l_{h_2,1}}$ -strongly concave.

744 Moreover $D(\mu)$ is $(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}})$ -smooth as

$$\begin{aligned} D(\mu_1) - D(\mu_2) &= -h_2^*(-A\mu_1) - (-h_2^*(-A\mu_2)) - h_1(\mu_1) + h_1(\mu_2) \\ &\leq \left\langle \frac{\partial -h_2^*(-A\mu_2)}{\partial -A\mu_2}, -A\mu_1 - (-A\mu_2) \right\rangle + \frac{1/\alpha_{h_2}}{2} \|-A\mu_1 - (-A\mu_2)\|^2 \\ &\quad + \langle -\nabla h_1(\mu_2), \mu_1 - \mu_2 \rangle + \frac{l_{h_1,1}}{2} \|\mu_1 - \mu_2\|^2 \\ &\leq \langle \nabla D(\mu_2), \mu_1 - \mu_2 \rangle + \frac{l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}}}{2} \|\mu_1 - \mu_2\|^2. \end{aligned}$$

745 The first inequality holds as both h_2^* and h_1 are smooth. The second follows the chain rule.

746 Note $\sigma_{\max}(A) \geq \sigma_{\min}(A) > 0$ as A is full column rank. This completes the proof. \square

747 In this way, we are ready to proceed with the general convergence analysis to solve (39) as $L(\mu, y)$
 748 using Algorithm 2 without acceleration and $T_y = 1$, which is a single-loop algorithm.

749 *Proof of Theorem 7.* We first look into the update of $\|y_t - \nabla h_2^*(-A\mu_t)\|$.

750 Fixing μ , define $y_\mu^* := \arg \min_y L(\mu, y)$. The first-order stationary optimality condition requires
 751 $\nabla_y L(\mu, y_\mu^*) = 0$, i.e. $\nabla h_2(y_\mu^*) = -A\mu_t$. This implies $y_\mu^* = \nabla h_2^*(-A\mu_t)$ because the mapping ∇h_2
 752 and ∇h_2^* are the inverse of each other according to Lemma 4.

753 For a fixed μ_t , the update rule $y_{t+1} = y_t - \eta_1 \nabla_y L(\mu_t, y_t)$ is a gradient descent step for the objective
 754 function $L(\mu_t, y)$, which is also α_{h_2} -strongly convex and $l_{h_2,1}$ -smooth to y . Following Lemma 7,
 755 take $\eta_1 \leq \frac{1}{l_{h_2,1}}$, we have

$$\|y_{t+1} - \nabla h_2^*(-A\mu_t)\| \leq (1 - \eta_1 \alpha_{h_2} / 2) \|y_t - \nabla h_2^*(-A\mu_t)\| \quad (40)$$

756 Following triangle inequality, we also have

$$\begin{aligned}
& \|y_{t+1} - \nabla h_2^*(-A\mu_{t+1})\| \\
& \leq \|y_{t+1} - \nabla h_2^*(-A\mu_t)\| + \|\nabla h_2^*(-A\mu_t) - \nabla h_2^*(-A\mu_{t+1})\| \\
& \leq (1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\| + \frac{\sigma_{\max}(A)}{\alpha_{h_2}} \|\mu_{t+1} - \mu_t\|
\end{aligned} \tag{41}$$

757 where the second term in the last inequality comes from the smoothness of the conjugate function
758 according to Lemma 4

759 We then look into the update of $\|\mu_{t+1} - \mu_t\|$. According to Lemma 12

$$D(\mu) := \min_{y \in \mathbb{R}^{d_y}} -h_1(\mu) + y^\top A\mu + h_2(y) = -h_1(\mu) - h_2^*(-A\mu)$$

760 is $\frac{\sigma_{\min}^2(A)}{l_{h_2,1}}$ -strongly concave and $(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}})$ -smooth with respect to μ . Moreover, the problem

$$\max_{\mu \in \mathbb{R}_+^{d_c}} D(\mu),$$

761 is equivalent to the unconstrained problem with the Lagrange multiplier

$$\max_{\mu \in \mathbb{R}^{d_c}} \tilde{D}(\mu) := D(\mu) + \lambda^\top \mu$$

762 where unique λ is non-negative and finite in all dimension, i.e. $0 \leq \lambda < \infty$, as $D(\mu)$ is strongly
763 convex and $\mu \in \mathbb{R}_+^{d_c}$ is equivalent to $\mu \geq 0$. We know that $\tilde{D}(\mu)$ is smooth and strongly concave
764 with the same modulus as $D(\mu)$. The first-order stationary condition requires

$$\nabla \tilde{D}(\mu^*) = \nabla D(\mu^*) + \lambda = 0. \tag{42}$$

765 In this way,

$$\begin{aligned}
& \frac{1}{\eta_2} \|\mu_{t+1} - \mu_t\| = \frac{1}{\eta_2} \|\mu_t + \eta_2(-\nabla h_1(\mu_t) + A^\top y_{t+1})\|_{\mathbb{R}_+^{d_c}} - \mu_t\| \\
& \stackrel{(a)}{\leq} \|-\nabla h_1(\mu_t) + A^\top y_{t+1}\| \\
& = \|-\nabla h_1(\mu_t) + A^\top \nabla h_2^*(-A\mu_t) + \lambda + A^\top y_{t+1} - A^\top \nabla h_2^*(-A\mu_t) - \lambda\| \\
& \stackrel{(b)}{\leq} \|\nabla \tilde{D}(\mu_t)\| + \sigma_{\max}(A) \|y_{t+1} - \nabla h_2^*(-A\mu_t)\| + \|\lambda\| \\
& \stackrel{(c)}{\leq} \|\nabla \tilde{D}(\mu_t) - \nabla \tilde{D}(\mu^*)\| + \sigma_{\max}(A)(1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\| + \|\lambda\| \\
& \stackrel{(d)}{\leq} (l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}}) \|\mu_t - \mu^*\| + \sigma_{\max}(A)(1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\| + \|\lambda\|
\end{aligned} \tag{43}$$

766 Inequality (a) comes from the non-expansiveness (1-Lipschitzness) of the projection operation, (b)
767 follows triangle inequality, (c) uses (42) and (40), and (d) comes from the smoothness of $\tilde{D}(\mu)$.

768 Now we are ready to find the bound of the update of $\|\mu_t - \mu^*\|$.

769 Define an auxiliary update as

$$\tilde{\mu}_{t+1} := [\mu_t + \eta_2 \nabla D(\mu_t)]_{\mathbb{R}_+^{d_c}} = [\mu_t + \eta_2(-\nabla h_1(\mu_t) + A^\top \nabla h_2^*(-A\mu_t))]_{\mathbb{R}_+^{d_c}}. \tag{44}$$

770 This is a projected gradient descent on strongly convex $-D(\mu)$. As $\mathbb{R}_+^{d_c}$ is closed and convex,
771 following Lemma 7, for $\eta_2 \leq \frac{1}{(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}})}$, we have

$$\|\tilde{\mu}_{t+1} - \mu^*\| \leq \left(1 - \eta_2 \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}}\right) \|\mu_t - \mu^*\|.$$

772 As the real update is $\mu_{t+1} = [\mu_t + \eta_2(-\nabla h_1(\mu_t) + A^\top y_t)]_{\mathbb{R}_+^{d_c}}$, by the non-expansiveness (1-
773 Lipschitzness) of projection operation, we have

$$\|\mu_{t+1} - \mu_t\| \leq \|\eta_2 A^\top (y_{t+1} - \nabla h_2^*(-A\mu_t))\| \leq \eta_2 \sigma_{\max}(A) \|y_{t+1} - \nabla h_2^*(-A\mu_t)\|$$

774 By triangle inequality and (40), we have

$$\begin{aligned} \|\mu_{t+1} - \mu^*\| &\leq \left(1 - \eta_2 \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}}\right) \|\mu_t - \mu^*\| + \eta_2 \sigma_{\max}(A) \|y_{t+1} - \nabla h_2^*(-A\mu_t)\| \\ &\leq \left(1 - \eta_2 \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}}\right) \|\mu_t - \mu^*\| + \eta_2 \sigma_{\max}(A) (1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\|. \end{aligned} \quad (45)$$

775 For some positive $\rho > 0$, denote

$$P_t := \rho \|\mu_t - \mu^*\| + \|y_t - \nabla h_2^*(-A\mu_t)\|. \quad (46)$$

776 We know from (41), (43), and (45) that

$$\begin{aligned} P_{t+1} &= \rho \|\mu_{t+1} - \mu^*\| + \|y_{t+1} - \nabla h_2^*(-A\mu_{t+1})\| \\ &\leq \rho \left(\left(1 - \eta_2 \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}}\right) \|\mu_t - \mu^*\| + \eta_2 \sigma_{\max}(A) (1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\| \right) \\ &\quad + (1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\| \\ &\quad + \frac{\sigma_{\max}(A)}{\alpha_{h_2}} \eta_2 \left(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \right) \|\mu_t - \mu^*\| + \sigma_{\max}(A) (1 - \eta_1 \alpha_{h_2}/2) \|y_t - \nabla h_2^*(-A\mu_t)\| + \|\lambda\| \Big) \\ &\leq \left(1 - \eta_2 \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}} + \frac{1}{\rho} \frac{\sigma_{\max}(A)}{\alpha_{h_2}} \eta_2 \left(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \right) \right) \rho \|\mu_t - \mu^*\| \\ &\quad + (1 - \eta_1 \alpha_{h_2}/2) \left(1 + \rho \eta_2 \sigma_{\max}(A) + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \eta_2 \right) \|y_t - \nabla h_2^*(-A\mu_t)\| + \frac{\sigma_{\max}(A)}{\alpha_{h_2}} \eta_2 \|\lambda\|. \end{aligned}$$

777 To construct $P_{t+1} \leq (1-c)P_t + \frac{\sigma_{\max}(A)}{\alpha_{h_2}} \eta_2 \|\lambda\|$ for some $0 < c < 1$, it is sufficient to find

778 $\eta_1 \leq \frac{1}{l_{h_2,1}}$, $\eta_2 \leq \frac{1}{(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}})}$, and $\rho > 0$ such that

$$\begin{cases} 0 < \left(1 - \eta_2 \frac{\sigma_{\min}^2(A)}{2l_{h_2,1}} + \frac{1}{\rho} \frac{\sigma_{\max}(A)}{\alpha_{h_2}} \eta_2 \left(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \right) \right) \leq 1 - \eta_2 \frac{\sigma_{\min}^2(A)}{4l_{h_2,1}} < 1 \\ 0 < (1 - \eta_1 \alpha_{h_2}/2) \left(1 + \rho \eta_2 \sigma_{\max}(A) + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \eta_2 \right) \leq (1 - \eta_1 \alpha_{h_2}/2) (1 + \eta_1 \alpha_{h_2}/2) < 1 \end{cases}$$

779 This can be obtained when

$$\begin{cases} \rho \geq \frac{4l_{h_2,1} \sigma_{\max}(A)}{\alpha_{h_2} \sigma_{\min}^2(A)} \left(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \right) \\ \eta_2 \leq \frac{1}{2 \left(\rho \sigma_{\max}(A) + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \right)} \end{cases} \quad (47)$$

780 (47) can be obtained when $\epsilon > 0$ is sufficiently such that $\rho = \epsilon^{-1} \geq \frac{4l_{h_2,1} \sigma_{\max}(A)}{\alpha_{h_2} \sigma_{\min}^2(A)} \left(l_{h_1,1} + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \right)$,

781 $\eta_1 = O(\frac{1}{l_{h_2,1}})$ and $\eta_2 = O(\frac{\alpha_{h_2}}{l_{h_2,1}} \rho^{-1}) = O(\epsilon^{-1})$. In this way,

$$P_{t+1} \leq (1-c)P_t + O(\alpha_{h_2}^{-1} \epsilon)$$

782 where $c > 0$ is of the order $O(\epsilon)$. Iteration gives

$$P_t \leq (1-c)^t P_0 + O(\alpha_{h_2}^{-1}). \quad (48)$$

783 Notice $P_0 = O(\epsilon^{-1})$ as $\rho = \epsilon^{-1}$. In this way, there exist $T_1 = O(\log(\epsilon^{-1}))$ such that for all $t > T_1$,

784 $(1-c)^t P_0 = O(1)$ and accordingly

$$P_t = O(1), \quad \forall t > T_1. \quad (49)$$

785 Moreover, as $P_t = \epsilon^{-1} \|\mu_t - \mu^*\| + \|y_t - \nabla h_2^*(-A\mu_t)\|$,

$$\|\mu_t - \mu^*\| \leq \epsilon P_t = O(\epsilon), \quad \forall t > T_1. \quad (50)$$

786 Furthermore, choose $\eta_1 = O(\frac{1}{l_{h_2,1}})$ satisfying $\eta_1 \leq \frac{1}{l_{h_2,1}}$, for $t > T_1$,

$$\|y_t - \nabla h_2^*(-A\mu_t)\| \leq (1 - \eta_1 \alpha_{h_2}/2)^{t-T_1} \|y_{T_1} - \nabla h_2^*(-A\mu_{T_1})\| + O(\epsilon). \quad (51)$$

787 Here $\eta_1 \alpha_{h_2} / 2 = O(\frac{\alpha_{h_2}}{l_{h_2,1}}) = O(1)$. In this way, for another $T_2 = O(\log(\epsilon^{-1}))$ steps, we have:

$$\|y_t - \nabla h_2^*(-A\mu_t)\| = O(\epsilon), \quad (52)$$

$$\text{and } \|y_t - y^*\| \leq \|y_t - \nabla h_2^*(-A\mu_t)\| + \|\nabla h_2^*(-A\mu_t) - \nabla h_2^*(-A\mu^*)\| \quad (53)$$

$$\leq \|y_t - \nabla h_2^*(-A\mu_t)\| + \frac{\sigma_{\max}^2(A)}{\alpha_{h_2}} \|\mu_t - \mu^*\| \quad (54)$$

$$= O(\epsilon + \alpha_{h_2}^{-1}\epsilon) = O(\epsilon) \quad (55)$$

788 we can see that the algorithm converges linearly with complexity $O(T_1 + T_2) = O(\log(\epsilon^{-1}))$. In
789 this way, obtaining

$$\|y_T - y^*\|^2 < \epsilon \quad \text{and} \quad \|\mu_T - \mu^*\|^2 < \epsilon, \quad (56)$$

790 requires complexity $T = O(\log((\sqrt{\epsilon})^{-1})) = O(\log(\epsilon^{-1}))$. This completes the proof. \square

791 E Applications to SVM model training

792 In this section, we provide further details about the SVM model training experiment for the linear
793 SVM model, including the problem formulation, and detailed results analysis.

794 E.1 Problem introduction

795 The SVM is a supervised machine learning model used for classification and regression tasks. It works
796 by finding the optimal hyperplane that separates data points of different classes with the maximum
797 margin. For the hard-margin SVM, misclassification is not tolerated. For the soft-margin SVM, the
798 violation of classification, ξ , is penalized to the training objective to consider misclassification. To
799 train an efficient soft-margin linear SVM, we are interested in the following constraint BLO problem

$$\min_c \mathcal{L}_{\mathcal{D}_{val}}(w^*, b^*) = \sum_{(z_{val,i}, l_{val,i}) \in \mathcal{D}_{val}} \exp(1 - l_{val,i}(z_{val,i}^\top w^* + b^*)) \quad (57a)$$

$$\text{with } w^*, b^*, \xi^* = \arg \min_{w, b, \xi} \frac{1}{2} \|w\|^2 + \frac{1}{2} \|c\|^2 \quad (57b)$$

$$\text{s.t. } l_{tr,i}(z_{tr,i}^\top w + b) \geq 1 - \xi_i \quad \forall i \in \{1, \dots, |\mathcal{D}_{tr}|\} \quad (57c)$$

$$\xi_i \leq c_i \quad \forall i \in \{1, \dots, |\mathcal{D}_{tr}|\}. \quad (57d)$$

800 The upper-level objective is a validation loss, and the lower level is to train SVM on the training
801 set $\mathcal{D}_{tr} := \{(z_{tr,i}, l_{tr,i})\}_{i=1}^{|\mathcal{D}_{tr}|}$ with the soft margin upper bounded by c . The lower-level objective
802 function considers both maximizing the margin (minimizing $\|w\|^2$) and allowing violations to
803 the separating hyperplane ξ , controlled by the hyperparameter (and upper-level variable) c . The
804 idea behind the BLO formulation is to use the validation loss (upper-level objective) to tune the
805 hyperparameter c , while the model parameters (lower-level variables) should be optimal in the training
806 dataset.

807 E.2 Additional Experiments

808 In this section, we present the detailed experimental results for the SVM model training experiment
809 using our BLOCC algorithm in comparison with two baselines, LV-HBA [69] and GAM [67], both
810 are tailored for BLO problems with inequality coupled constraints.

811 We evaluate the proposed algorithms in two different datasets: diabetes [18] and fourclass [27]. The
812 detailed results are illustrated in Figure 4, where we represent validation metrics in the left column
813 and test metrics in the right column. The metrics include both loss and accuracy, for both the diabetes
814 and fourclass datasets. Our algorithm is able to converge faster both in terms of accuracy and loss,
815 and it achieves a lower loss value than the alternatives for both datasets in both validation and test.

816 VT: Simply to showcase different things. They can be unified if we consider so.

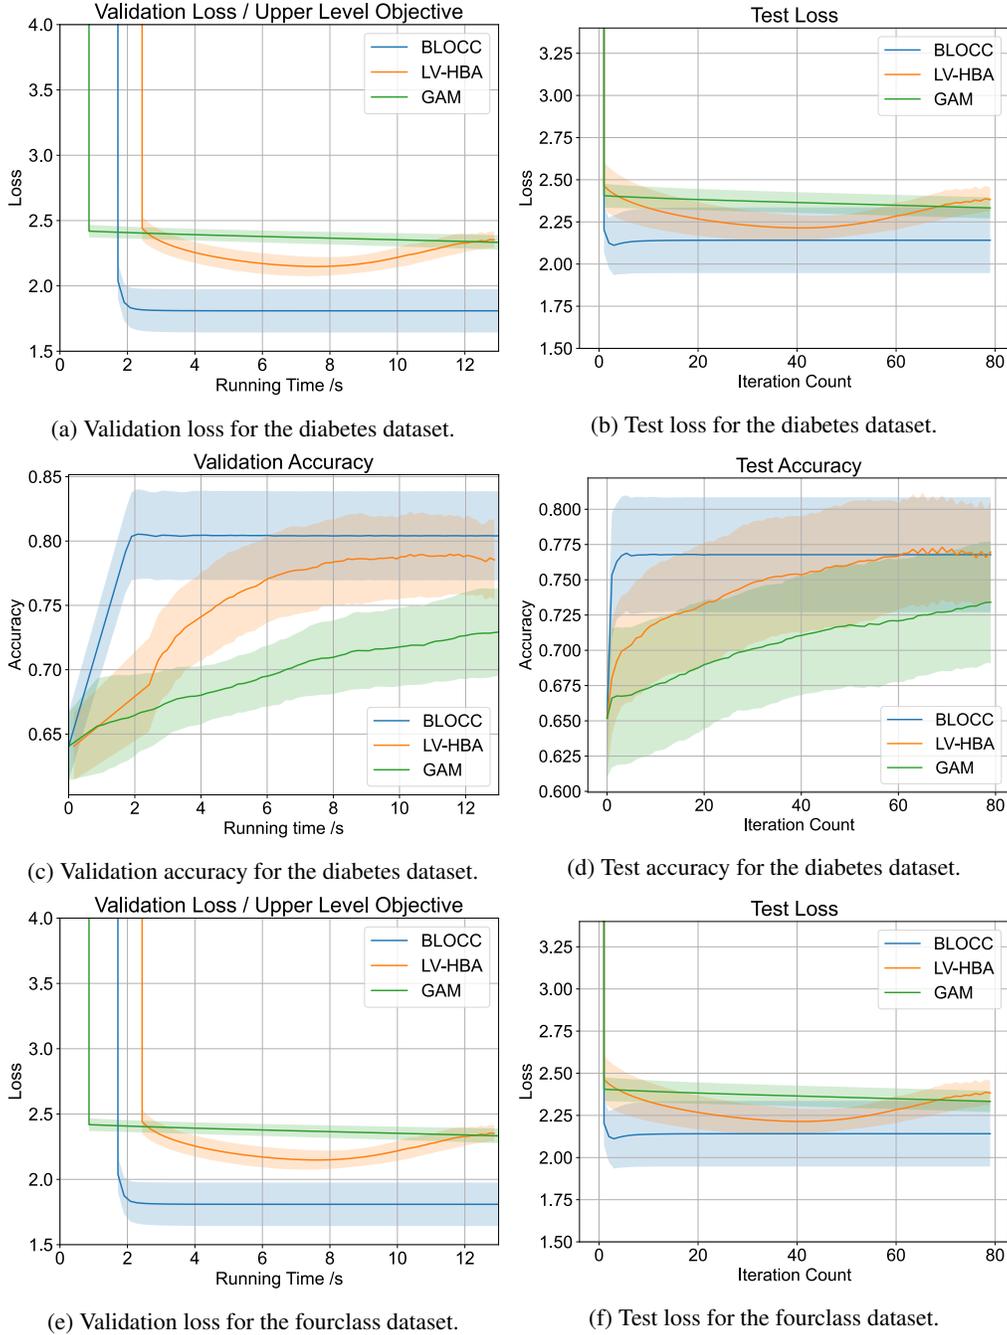

Figure 4: Results of the hyperparameter optimization experiment with an SVM model.

817 **F Applications to Transportation Network Planning**

818 This section delves into applying the proposed algorithm to tackle a practical BLO problem in
 819 transportation science.

820 **F.1 Problem introduction**

821 In this transportation network planning problem, we are to design a capacitated transportation network
 822 connecting a set \mathcal{S} of stations [9]. The network is designed to carry out passengers from a given

823 origin $o \in \mathcal{S}$ to a given destination $d \in \mathcal{S}$. For all the potential (o, d) -markets, we know the estimated
824 demand of passengers, who can choose rationally among \mathcal{N} networks including our designed network
825 and the ones of our competitors', considering their trip (dis)utility function that depends on factors
826 such as the price or the trip time [9].

827 Our goal is to maximize the operator's benefit modeled by a utility function (upper-level objective)
828 knowing the passengers make the rational decisions on choosing the best route (lower-level objective)
829 considering the available options (coupled constraints). Specifically, the network designer must
830 determine the capacity for each link $(i, j) \in \mathcal{A}$, where \mathcal{A} denotes the proposed network topology
831 ($\mathcal{A} \subseteq \mathcal{S} \times \mathcal{S}$). The set \mathcal{K} defines the markets between various origins o and destinations d , such that
832 $(o, d) \in \mathcal{K}$ and $\mathcal{K} \subseteq \mathcal{S} \times \mathcal{S}$. The problem entails the joint optimization of construction and flow
833 variables, which are described below.

- 834 • $x_{ij} \in \mathbb{R}^+$: capacity constructed for the link $(i, j) \in \mathcal{A}$.
- 835 • $y^{od} \in [0, 1]$: proportion of passengers from market $(o, d) \in \mathcal{K}$ choosing the new network
836 for their travel. As we just consider 2 networks, the proportion of passengers choosing the
837 incumbent network is $1 - y^{od}$.
- 838 • $y_{ij}^{od} \in [0, 1]$: proportion of passengers from market $(o, d) \in \mathcal{K}$ using link $(i, j) \in \mathcal{A}$ for
839 their travel.

840 To be consistent with the rest of the manuscript, we use x to denote a tuple collecting all the
841 construction variables so that x represents the set of variables in the upper-level (associated with
842 the decisions of the operator). The feasible domain for x is $\mathcal{X} = \mathbb{R}^{+|\mathcal{A}|}$. Analogously, we use y to
843 denote a tuple collecting all the flow variables. Tuple y represents the variables for the lower-level
844 (associated with the passengers' decisions). The feasible domain for y is $\mathcal{Y} = [0, 1]^{|\mathcal{A}|} \times [0, 1]^{|\mathcal{A}||\mathcal{K}|}$.

845 In addition to the optimization variables, our objective and constraints involve other state variables
846 and parameters:

- 847 • w^{od} : total estimated demand (number of passengers) between nodes $(o, d) \in \mathcal{K}$.
- 848 • m^{od} : revenue obtained by the operator from a passenger in the market $(o, d) \in \mathcal{K}$.
- 849 • c_{ij} : construction cost per passenger associated with link $(i, j) \in \mathcal{A}$.
- 850 • t_{ij} : travel time for the link $(i, j) \in \mathcal{A}$.
- 851 • t_{ext}^{od} : travel time on the alternative network for passengers in the market $(o, d) \in \mathcal{K}$.
- 852 • ω_t : coefficient associated with the travel time on passengers' utility function.

853 Now we are ready to introduce the objectives of our BLO problem. The network operator aims at
854 maximizing profits and minimizing costs. As a result we have that the objective to minimize is

$$\min_{x,y} f(x, y) := - \left(\sum_{\forall (o,d) \in \mathcal{K}} m^{od} y^{od*}(x) - \sum_{\forall (i,j) \in \mathcal{A}} c_{ij} x_{ij} \right), \quad (58)$$

855 where $y^{od*}(x)$ are the passenger flows associated with the network design x . Regarding the lower
856 level, for each transportation alternative and market, passengers aim to minimize the function

$$\min_{x,y} g(x, y) := w^{od} y^{od} (\log(y^{od}) - 1) + \sum_{(i,j) \in \mathcal{A}} w^{od} \omega_t t_{ij} y_{ij}^{od} \quad (59)$$

857 The second term represents the passenger's disutility. The role of the negative entropy in the first
858 term is to ensure that decisions are made according to the so-called logit model [4]-[10]. This model
859 states that the probability that a passenger selects network $n \in \mathcal{N}$ for market (o, d) is determined by
860 the logit distribution:

$$P(n|(o, d)) = \frac{e^{-u_n^{od}}}{\sum_{n' \in \mathcal{N}} e^{-u_{n'}^{od}}}, \quad (60)$$

861 where u_n^{od} represents the disutility of the best available path within network $n \in \mathcal{N}$ for market
862 $(o, d) \in \mathcal{K}$. For this study, we assume a scenario where: i) the disutility is given by the multiplication

863 of the sensitivity parameter ω_t and the travel time and ii) only one incumbent network exists, thus
 864 \mathcal{N} consists of this incumbent network and the network under construction. Interestingly, it can be
 865 rigorously shown that the Karush-Kuhn-Tucker (KKT) conditions associated with of (59) lead to the
 866 expression in (60); see a formal proof of this result in [51].

867 With these considerations in mind, we are ready to formulate our constrained BLO problem

$$\min_{x \in \mathcal{X}} - \sum_{\forall (o,d) \in \mathcal{K}} m^{od} y^{od*} + \sum_{\forall (i,j) \in \mathcal{A}} c_{ij} x_{ij} \quad (61a)$$

s.t.

$$(y^{od*}, y_{ij}^{od*}) = \arg \min_{y \in \mathcal{Y}} \sum_{(o,d) \in \mathcal{K}} w^{od} y^{od} (\log(y^{od}) - 1) \quad (61b)$$

$$+ \sum_{(o,d) \in \mathcal{K}} w^{od} (1 - y^{od}) (\log(1 - y^{od}) - 1)$$

$$+ \sum_{(o,d) \in \mathcal{K}} \sum_{(i,j) \in \mathcal{A}} w^{od} \omega_t t_{ij} y_{ij}^{od} + \sum_{(o,d) \in \mathcal{K}} w^{od} \omega_t t_{ext}^{od} (1 - y^{od})$$

s.t.

$$\sum_{\forall (o,d) \in \mathcal{K}} w^{od} y_{ij}^{od} \leq x_{ij} \quad \forall (i,j) \in \mathcal{A} \quad (61c)$$

$$\sum_{\forall j | (i,j) \in \mathcal{A}} y_{ij}^{od} - \sum_{\forall j | (j,i) \in \mathcal{A}} y_{ji}^{od} = \begin{cases} y^{od} & \text{if } i = o \\ -y^{od} & \text{if } i = d \\ 0 & \text{otherwise} \end{cases} \quad \forall i, (o,d) \in \mathcal{S} \times \mathcal{K}, \quad (61d)$$

868 where (61a) is the (operator's) upper-level objective and (61b) is the (passengers') lower-level
 869 objective. Note that for the lower-level objective, we aggregated the terms in (59) for all markets in \mathcal{K}
 870 and the new and the alternative network, with the latter absorbing a fraction $(1 - y^{od})$ of the demand.

871 We shift now attention to the constraints. The capacity constraint in (61c) is critical for our approach
 872 since it relates to the upper and lower-level variables. Notice that we have one constraint per link
 873 and, in each of them $|\mathcal{K}|$ lower-level variables are involved. This implies that, even for medium-size
 874 networks (with tens or hundreds of nodes), thousands of coupled constraints, each with thousands
 875 of variables, will be present. In addition, (61d) represents flow conservation constraints: for every
 876 market $(o,d) \in \mathcal{K}$, these constraints ensure that the total flow departing from the origin o equals the
 877 total flow for that market. Similarly, the total flow entering destination d matches the flow leaving the
 878 origin. For nodes that are neither the origin nor the destination of the market, the flow conservation
 879 must be zero. The number of these constraints, which only involve lower-level variables, is $|\mathcal{S}||\mathcal{K}|$,
 880 scaling as a third-order polynomial with the number of nodes.

881 F.2 Experiment roadmap

882 In order to provide numerical results illustrating the behavior of our algorithm, we solve this opti-
 883 mization problem in three scenarios:

- 884 1. the design of a 3-node simple synthetic network;
- 885 2. the design of a 9-node synthetic network that has been previously analyzed in the transporta-
 886 tion literature; and,
- 887 3. the design of a (real-world) subway network for the city of Seville, Spain, with 24 nodes.

888 In the case of the 3-node network, we will conduct a comparative analysis against other algorithms to
 889 evaluate the efficacy of our approach. Moving on to the 9-node and Seville networks, we will provide
 890 insights into the performance and behavior of our algorithm under varying parameters, shedding light
 891 on the versatility and adaptability of our approach to real-world transportation networks.

892 While one of the goals of these experiments was to compare our BLOCC algorithm against LV-HBA
 893 [69] and GAM [67], for the scenario at hand, the GAM algorithm cannot be implemented, since the

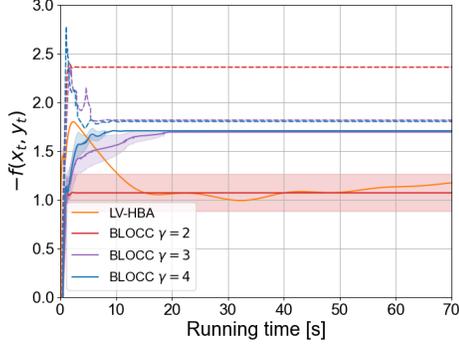

Figure 5: Negative upper-level objective $-f(x_t, y_t)$ evolution over time for a 3-node network design problem for 10 random initializations of the upper-level variables. The solid lines represent the mean value of $-f(x_t, y_{g,t}^{T_g})$ of the 10 realizations, and the shaded region is the \pm standard deviation. The dashed lines represent the mean value of $-f(x_t, y_{F,t}^{T_F})$ of the 10 realizations, and the shaded region is the \pm standard deviation. Three different γ values (red, purple, blue) are represented in our algorithm, and fixed stepsize $\eta = 1.6e - 4$. The orange color represents the evolution of $-f(x_t, y_t)$ for the LV-HBA algorithm.

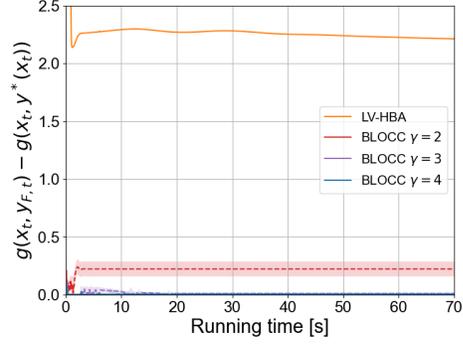

Figure 6: Loss of optimality on the lower-level optimization problem over time for a 3-node network design problem $g(x_t, y_t) - g(x_t, y_t^*)$, for 10 random initializations of the upper-level variables. The solid lines represent the mean value of the 10 realizations, the dashed lines represent performance of $g(x_t, y_{F,t}^{T_F}) - g(x_t, y_t^*)$, and the shaded region is the \pm standard deviation. Three different γ values (red, purple, blue) are represented in our algorithm, and fixed stepsize $\eta = 1.6e - 4$. The orange color represents the loss of optimality on the lower-level problem $g(x_t, y_t) - g(x_t, y_t^*)$ for the LV-HBA algorithm.

894 inverse of a matrix at each iteration for the problem in (61) is not tractable. In this way, we only
 895 conducted the experiments using our BLOCC and LV-HBA.

896 Moreover, besides the fact that Theorem 1 and Theorem 2 guarantees that $(x_T, y_{F,T}^{T_F})$ can be the
 897 solution to the ϵ -approximation problem, using $y_{g,T}^{T_g}$ as output can better attain the lower-level
 898 minimum $y_g^*(x_T)$ as it solves (7). In this way, we will presents both output using $y_{F,T}^{T_F}$ and $y_{g,T}^{T_g}$.

899 F.3 A 3-node network experiment

900 In this section, we solve the problem formulated in (61) using a network with 3 nodes, 6 potential
 901 links, and 6 markets. The state variable values for the simulation scenarios are available in the code
 902 repository. Figure 5 illustrates the performance of both algorithms, showing computation time on
 903 the horizontal axis and the upper-level objective value $-f(x_t, y_t)$ on the vertical axis for 10 random
 904 initializations. We analyze three instances of BLOCC with $\gamma \in 2, 3, 4$ and a stepsize of $\eta = 1.6e - 4$.
 905 The upper-level objective values are computed using $-f(x_t, y_{g,t}^{T_g})$ and $-f(x_t, y_{F,t}^{T_F})$.

906 Our algorithm converges to the local optimum faster than LV-HBA, which fails to reach this optimum
 907 within the given time limit, resulting in a solution that does not satisfy the lower-level optimality
 908 constraint (61b).

909 To better understand the results, we compare the main differences between BLOCC and LV-HBA:

- 910 1. In BLOCC, either using output $y_{g,T}^{T_g}$ or $y_{F,T}^{T_F}$ has a guarantee of attaining optimality at the
 911 lower level, whereas in LV-HBA, the lower-level optimality can not be guaranteed, as shown
 912 in Figure 6
- 913 2. As already mentioned, the LV-HBA algorithm requires a joint projection into $\{\mathcal{X} \times \mathcal{Y} :$
 914 $g^c(x, y) \leq 0\}$ at each iteration, so when there are a large number of upper variables (99 in
 915 the presented scenario) and also a large number of constraints (24 in this simplified scenario),
 916 the computational time required for this projection increases considerably. In contrast, in
 917 BLOCC, it is only necessary to project onto \mathcal{X} at each iteration, which simply represents
 918 box constraints and projection is straightforward.

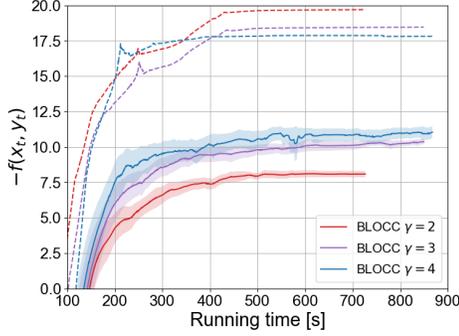

Figure 7: Negative upper-level objective $-f(x_t, y_t)$ evolution over time for a 9-node network design problem for 10 random initializations of the upper-level variables. The solid lines represent the mean value of $-f(x_t, y_{g,t}^{T_g})$ of the 10 realizations, and the shaded region is the \pm standard deviation. The dashed lines represent the mean value of $-f(x_t, y_{F,t}^{T_F})$ of the 10 realizations, and the shaded region is the \pm standard deviation. Three different γ values (red, purple, blue) are represented in our algorithm, and fixed stepsize $\eta = 1.6e - 4$.

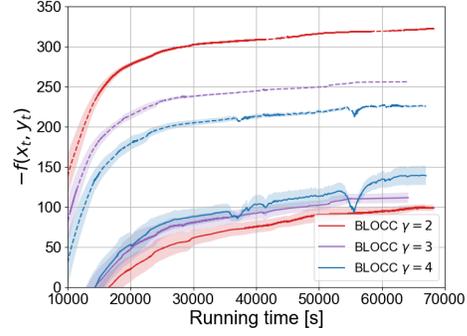

Figure 8: Negative upper-level objective $-f(x_t, y_t)$ evolution over time for a metro network design problem in the city of Seville, Spain, for 2 different random initializations of the upper-level variables. The solid lines represent the mean value of $-f(x_t, y_{g,t}^{T_g})$ of the 2 realizations, and the shaded region is the \pm standard deviation. The dashed lines represent the mean value of $-f(x_t, y_{F,t}^{T_F})$ of the 2 realizations, and the shaded region is the \pm standard deviation. Three different γ values (red, purple, blue) are represented in our algorithm, and fixed stepsize $\eta = 1.6e - 4$.

919 F.4 A 9-node network experiment

920 In this case, we consider a network with $|\mathcal{S}| = 9$ nodes and $|\mathcal{A}| = 72$ potential links, as well as
 921 $|\mathcal{K}| = 72$ markets. Figure 7 presents the obtained results for three different values of parameter
 922 $\gamma \in \{2, 3, 4\}$, and stepsize $\eta = 1.6e - 4$. It depicts computational time on the horizontal axis, while
 923 the evolution of $-f(x_t, y_{g,t}^{T_g})$ is provided on the vertical axis for 10 different random initializations of
 924 the upper-level variables. As in the previous network, BLOCC algorithm is able to converge, with
 925 different γ values leading to different optimums.

926 As mentioned in the main paper (reference main paper section), this parameter influences on the
 927 accuracy achieved regarding optimality at the lower-level for the variable y_F . For higher values of
 928 γ , the optimality condition at the lower-level when solving the problem associated with (reference
 929 algorithm 2) becomes more important in the objective function. Thus, the difference between $y_{g,t}^{T_g}$
 930 and $y_{F,t}^{T_F}$ decreases for higher values of γ . Additionally, it can be seen how the best objective value
 931 $-f(x_t, y_{g,T}^{T_g}(x))$ is achieved for the highest value of γ , as well as the accuracy on the optimality of
 932 the lower-level problem for the solution of $y_{F,t}^{T_F}$ increases.

933 F.5 Seville network experiment

934 In this section, we aim to demonstrate the validity of BLOCC by applying it to a real transportation
 935 network design problem. Specifically, we address the design of a potential metro network in the city
 936 of Seville. This network consists of $|\mathcal{S}| = 24$ nodes and 552 possible links. However, we filter the set
 937 of possible links according to two criteria:

- 938 1. The link between nodes $(i, j) \in \mathcal{S} \times \mathcal{S}$ can only exist if node j is one of the 3 closest
 939 neighbors to i , or vice versa, in terms of travel time.
- 940 2. The link between nodes $(i, j) \in \mathcal{S} \times \mathcal{S}$ can only exist if the travel time t_{ij} is less than 7
 941 minutes.

942 Thus, the set of possible links is reduced to $|\mathcal{A}| = 88$ possible links. The proposed topology for the
 943 network is shown in Figure 9. We consider all possible markets between nodes, so $|\mathcal{K}| = 552$.

944 Following the narrative in Sections [F.3](#) and [F.4](#),
 945 Figure [8](#) presents the evolution of the upper-
 946 level objective function with time for values of
 947 the parameter $\gamma \in \{2, 3, 4\}$ for 2 different real-
 948 izations. As it can be observed, higher values of
 949 $-f(x_T, y_{T,g}^{T_g})$ are obtained for higher values of
 950 γ , as well as smaller gaps between $f(x_T, y_{T,g}^{T_g})$
 951 and $-f(x_T, y_{T,F}^{T_F})$. In summary, it is demon-
 952 strated that the algorithm formulated in this docu-
 953 ment is able to solve problems with a large
 954 number of variables, which can have practical
 955 value in real-world applications, such as the one
 956 studied in this section.

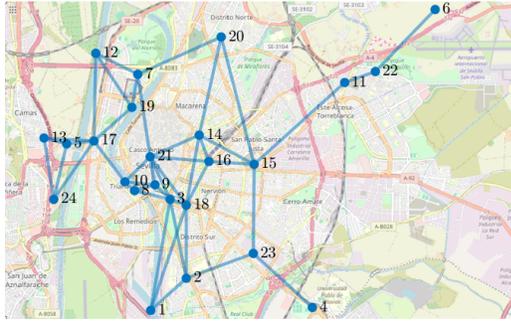

Figure 9: Topology of the Seville network.

957 NeurIPS Paper Checklist

958 1. Claims

959 Question: Do the main claims made in the abstract and introduction accurately reflect the
 960 paper’s contributions and scope?

961 Answer: [\[Yes\]](#)

962 Justification: The abstract and introduction clearly state the claims made, including the
 963 contributions made in the paper and important assumptions and limitations.

964 2. Limitations

965 Question: Does the paper discuss the limitations of the work performed by the authors?

966 Answer: [\[Yes\]](#)

967 Justification: yes, we have discussed in the conclusions.

968 3. Theory Assumptions and Proofs

969 Question: For each theoretical result, does the paper provide the full set of assumptions and
 970 a complete (and correct) proof?

971 Answer: [\[Yes\]](#)

972 Justification: All have been clearly listed.

973 4. Experimental Result Reproducibility

974 Question: Does the paper fully disclose all the information needed to reproduce the main ex-
 975 perimental results of the paper to the extent that it affects the main claims and/or conclusions
 976 of the paper (regardless of whether the code and data are provided or not)?

977 Answer: [\[Yes\]](#)

978 Justification: The supplementary materials contain the code used to run the simulations.

979 5. Open access to data and code

980 Question: Does the paper provide open access to the data and code, with sufficient instruc-
 981 tions to faithfully reproduce the main experimental results, as described in supplemental
 982 material?

983 Answer: [\[Yes\]](#)

984 Justification: the supplementary materials contain all the code used to run the simulation, as
 985 well as the data files considered.

986 6. Experimental Setting/Details

987 Question: Does the paper specify all the training and test details (e.g., data splits, hyper-
 988 parameters, how they were chosen, type of optimizer, etc.) necessary to understand the
 989 results?

990 Answer: [\[Yes\]](#)

991 Justification: all the necessary details to run the experiments are available in the code.

992 **7. Experiment Statistical Significance**
993 Question: Does the paper report error bars suitably and correctly defined or other appropriate
994 information about the statistical significance of the experiments?
995 Answer: [Yes]
996 Justification: the figures in the paper include confidence intervals representing the standard
997 deviation for different realizations of the experiments. Also the tables include the standard
998 deviation of the simulations.

999 **8. Experiments Compute Resources**
1000 Question: For each experiment, does the paper provide sufficient information on the com-
1001 puter resources (type of compute workers, memory, time of execution) needed to reproduce
1002 the experiments?
1003 Answer: [NA]
1004 Justification: the paper is theory paper, and does not include much computation-heavy
1005 experiments

1006 **9. Code Of Ethics**
1007 Question: Does the research conducted in the paper conform, in every respect, with the
1008 NeurIPS Code of Ethics <https://neurips.cc/public/EthicsGuidelines?>
1009 Answer: [Yes]
1010 Justification: we follow the NeurIPS Code of Ethics.

1011 **10. Broader Impacts**
1012 Question: Does the paper discuss both potential positive societal impacts and negative
1013 societal impacts of the work performed?
1014 Answer: [NA]
1015 Justification: the work is foundational research, and there is no societal impact of the work
1016 performed.

1017 **11. Safeguards**
1018 Question: Does the paper describe safeguards that have been put in place for responsible
1019 release of data or models that have a high risk for misuse (e.g., pretrained language models,
1020 image generators, or scraped datasets)?
1021 Answer: [NA]
1022 Justification: the paper poses no such risks.

1023 **12. Licenses for existing assets**
1024 Question: Are the creators or original owners of assets (e.g., code, data, models), used in
1025 the paper, properly credited and are the license and terms of use explicitly mentioned and
1026 properly respected?
1027 Answer: [NA]
1028 Justification: the paper does not use existing assets.

1029 **13. New Assets**
1030 Question: Are new assets introduced in the paper well documented and is the documentation
1031 provided alongside the assets?
1032 Answer: [NA]
1033 Justification: the paper does not release new assets.

1034 **14. Crowdsourcing and Research with Human Subjects**
1035 Question: For crowdsourcing experiments and research with human subjects, does the paper
1036 include the full text of instructions given to participants and screenshots, if applicable, as
1037 well as details about compensation (if any)?
1038 Answer: [NA]
1039 Justification: the paper does not involve crowdsourcing nor research with human subjects.

1040 **15. Institutional Review Board (IRB) Approvals or Equivalent for Research with Human**
1041 **Subjects**

1042 Question: Does the paper describe potential risks incurred by study participants, whether
1043 such risks were disclosed to the subjects, and whether Institutional Review Board (IRB)
1044 approvals (or an equivalent approval/review based on the requirements of your country or
1045 institution) were obtained?

1046 Answer: [NA] .

1047 Justification: the paper does not involve crowdsourcing nor research with human subjects.

1048
